2. Registration of a Birth.—Within forty-two days after the birth of a child in England and Wales, information for the registration must be given to the Registrar of Births and Deaths for the sub-district in which the birth occurred. The duty of giving this information and of signing the birth register rests primarily upon the parents, or, failing them, on the occupier of the house or institution where the birth occurred, or a person present at the birth, or the person having charge of the child. As a rule the registrar will expect either the father or the mother to attend and give him the information, but in the case of an illegitimate child the father is not qualified to give information alone, but he can attend with the mother and sign the birth entry jointly with her.

The information recorded in the register includes the date and place of the birth, the name and sex of the child, the name, surname, and occupation of the father, and the name, surname, and maiden surname of the mother. However, if the child is of illegitimate birth, no particulars relating to the father will be inserted in the entry unless both he and the mother request it and both sign the register.

No fee is payable when a birth is registered within three months after its occurrence, but after three months have elapsed an informant wishing to effect the registration must do so in the presence of the superintendent registrar of the district, and must pay fees amounting to 7*s*. 6*d*.

If twelve months have passed since the birth occurred, then it can be registered only on the authority of the Registrar General, to whom applications should be addressed. If registration is authorised, a fee of 15*s*. will be payable.

Instead of giving the information directly to the registrar of the sub-district in which the birth occurred, an informant may attend before any registrar in England and Wales (or before any superintendent registrar if three months have elapsed since the birth) to make a written declaration of the particulars which have to be registered. This will be sent on to the appropriate registrar, who will then make the entry in his register. A fee of 3*s*. is payable for this service.

When a birth has not been registered within forty-two days after its occurrence, the registrar may issue a formal requisition to a qualified informant, requiring him to attend before him to discharge his statutory duty to give information for the registration of the birth and to sign the register. The failure of a parent to register the birth of a child or of any qualified informant to comply with a registrar's requisition is a punishable offence.

3. Re-registration of Birth of Legitimated Person.—If the parents of an illegitimate person marry each other subsequent to the birth, and if the father is domiciled in England or Wales at the time of the marriage, then that person is legitimated by virtue of the marriage. Further, if the legitimated person was born in England or Wales, the parents have a duty to apply to the Registrar General for the re-registration of the birth within three months after the date of the marriage. If application is made within this time, re-registration, if authorised, will be effected free of charge, but if application is made later a fee not exceeding 10*s*. may be payable. The new birth entry will be similar to that for a legitimate child.

If application is not made by *both* parents, re-registration cannot be authorised unless the original birth entry was signed jointly by both parents, or the paternity of the child was established by an affiliation order, or a declaration of legitimacy has been obtained in the High Court or in a County Court.

4. Birth Certificates.—Birth certificates relating to the child may be obtained from the registrar as soon as the birth has been registered. A full copy of the entry can be supplied at the time of registration for a fee of 3*s*. 9*d*., but if application is made at a later date a search fee will normally be payable in addition. This will be 1*s*. 6*d*. if the applicant goes personally to the register office or to the General Register Office, Somerset House, or 3*s*. 9*d*. if he applies by post. Birth certificates required for certain statutory purposes are obtainable from the registrar of the sub-district where the birth occurred, or from the district superintendent registrar, at special fees of 6*d*. or 1*s*.

A shortened form of birth certificate is obtainable for a fee of 9*d*. This gives no information about parentage, but states only the name, sex, date and place of birth of the person concerned. Short birth certificates are now in general use throughout the country, and are acceptable on almost all occasions when a person needs to prove his age.

5. Registration of Still-births.—A still-born child is a child which has issued forth from its mother after the twenty-eighth week of pregnancy, and which did not at any time after being completely expelled from its mother breathe or show any other signs of life. As in the case of a live birth, the duty of giving information for the registration of the birth of a still-born child rests primarily on the parents or, failing them, on the occupier of the house or institution where the still-birth occurred, or a person present at the birth. There is no provision for the registration of a still-birth before any registrar other than the one for the sub-district in which the birth occurred, and he will require evidence that the birth was indeed a still-birth. This evidence should take the form of a certificate from the doctor or midwife who was in attendance at the birth or who has examined the body of the child, but if such a certificate cannot be obtained, then the informant will be required to make a declaration as to the facts.

6. Adopted Children Register.—An adoption Order granted by a court in England and Wales under the Adoption Act, 1958, contains a direction to the Registrar General to make an entry recording the adoption in the Adopted Children Register.

When the entry has been made, a full certificate containing the name, surname, date and country of birth of the adopted child, and particulars of the adoptive parents is obtainable from the General Register Office under the same conditions and for the same fee for a birth certificate.

A short certificate at a fee of 9*d*. may also be obtained. This bears no reference to the fact of adoption, and states only the child's name and surname, sex, date and place of birth.

DEATHS: REGISTRATION AND ARRANGEMENTS FOR BURIAL OR CREMATION (ENGLAND AND WALES)

1. Registration of a Death.—Every death taking place in England and Wales must be registered by the registrar of the sub-district in which the death occurred. Except in a case where a coroner's inquest has been held, information for the registration must be given personally to the registrar by a qualified informant within five days, or within fourteen days if an informant has sent a written notification of the death to the registrar. Qualified informants include relatives, any person present at the death, the occupier or inmate of the house or institution where the death occurred, or the person responsible for the arrangements for burial or cremation.

If the deceased person was attended during his last illness by a registered medical practitioner, then it is the duty of that doctor to sign and send to the registrar a medical certificate of the cause of death, and at the same time to give to a qualified informant of the death a notice that he has signed the certificate. This notice should be handed to the registrar by the informant when he attends to register the death.

If the death has been referred to the coroner, it cannot be registered until he has completed his investigations. When an inquest is held the registrar will register the death without the attendance of any informant on the authority of a document issued to him by the coroner.

The information recorded in the register includes the date and place of the death, the name, sex, age, and occupation of the deceased, and the cause of death.

2. Arrangements for Burial.—The body of a deceased person may not be buried until an

authority for the burial has been issued by the coroner or the registrar. A registrar will normally issue his authority after the death has been registered, but a certificate for burial can be obtained from the registrar *before* the registration of the death provided that he has received written notice of the death and a medical certificate of cause of death. If a death is being investigated by a coroner, a registrar cannot issue any authority for burial until those investigations have been completed.

3. Arrangements for Cremation.—The body of a deceased person may not be cremated until an authority for cremation has been issued by the coroner or the registrar. The coroner may issue his certificate for cremation or, after the death has been registered, the registrar may issue his authority, but neither of these documents in itself is sufficient authority to allow a cremation to proceed. Final authority for cremation must be given by a medical referee at the crematorium.

Cremation may not take place if the deceased has left written directions forbidding that form of disposal.

4. Removal of Bodies out of England and Wales.—Any person wishing to remove the body of a deceased person out of England and Wales must give notice to that effect to the coroner for the area within which the body is lying. The body may then be removed after the expiration of four clear days from the day on which the notice was received by the coroner, or earlier if the coroner states in his acknowledgment of the notice that no further enquiries by him are necessary. Forms for the purpose of giving notice to the coroner may be obtained from any Registrar of Births and Deaths.

5. Death Certificates.—Death certificates may be obtained from the registrar as soon as the death has been registered. A certificate can be supplied at the time of registration for a fee of 3*s.* 9*d.*, but if application is made at a later date a search fee will normally be payable in addition. This will be 1*s.* 6*d.* if the applicant goes personally to the register office or to the General Register Office, Somerset House, for the certificate, or 3*s.* 9*d.* if he applies by post. Death certificates required for certain statutory purposes are obtainable from the registrar of the sub-district where the death occurred, or from the district superintendent registrar, at a special fee of 1*s.*

MARRIAGES: PRELIMINARY FORMALITIES (ENGLAND AND WALES)

1. General.—In England and Wales, marriage may be celebrated between persons aged sixteen or over according to the rites and ceremonies of the Church of England after appropriate preliminaries, or according to any other rites or before a superintendent registrar after the appropriate civil preliminaries have been observed. A marriage may be solemnised at any time between 8 a.m. and 6 p.m.

2. Marriage According to the Rites of the Church of England.—The preliminaries to a Church of England marriage may be the publication of banns, the issue of a common licence, the issue of a special licence, or the issue of a superintendent registrar's certificate (see "Civil Preliminaries" below).

(a) *Banns.*—Application for the publication of banns should be made to the clergyman of the parish in which each party resides. The banns must be published on three Sundays preceding the solemnisation of the marriage, which should take place within three months after the completion of the publication of the banns.

(b) *Common Licence.*—Application for a common licence dispensing with the necessity for banns should be made to the Diocesan Registrar or any Surrogate for granting Marriage Licences in the Diocese, or a Surrogate of the Vicar General or of the Master of the Faculties. A common licence is void if the marriage is not solemnised within three months of its issue.

(c) *Special Licence.*—A special licence granted by or on behalf of the Archbishop of Canterbury enables a marriage to be solemnised according to the rites of the Church of England at any time and place. Such a licence is issued only in grave emergencies or very exceptional circumstances.

(d) *Superintendent Registrar's Certificate.*—A marriage according to the rites of the Church of England may be solemnised with the consent of the clergyman of the church on the authority of a certificate of a superintendent registrar instead of after the publication of banns (see "Civil Preliminaries" below).

If any further information is required concerning marriage according to the rites of the Church of England, application should be made to the clergyman of the church in which it is desired that the marriage shall take place.

3. Civil Preliminaries.—Marriage after civil preliminaries may be on the authority of a superintendent registrar's certificate without licence, or of his certificate and licence, and may be solemnised in a register office, in a registered building (*i.e.*, a place of worship which has been registered for the solemnisation of marriages), or according to the usages of the Jews or Quakers. A summary of the legal requirements before notice of marriage can be given is set out below. More detailed information can be obtained from the superintendent registrar of the district in which either party resides.

(a) *Superintendent Registrar's Certificate without Licence.*—When both parties reside in the same registration district each party must have had his or her usual place of residence within that district during the seven days immediately preceding the giving of the notice to the superintendent registrar. The notice may be given by either party.

If the parties reside in different districts, notice must be given to the superintendent registrar of each district. Each party may give notice in his or her district, or either party may give both notices, but notice cannot be given until the seven days' residential qualification has been completed.

Generally speaking, the building in which the marriage is to take place must be in the district of residence of the parties or of one of them, but there are certain exceptions to this.

On the request of the party who gave the notice, the superintendent registrar may issue his certificate, provided that a period of twenty-one days has elapsed since he entered the notice in his marriage notice book. The marriage may then take place in the building specified in the notice at any time within three months from the day on which the notice was entered in the book.

(b) *Superintendent Registrar's Certificate and Licence.*—Only one notice is required, whether the parties reside in the same or in different registration districts, and the notice may be given by either party, but both parties must be in England or Wales on the day notice is given. One of the parties must have resided in the registration district in which notice is given for fifteen days immediately preceding the giving of the notice, and the marriage must (with certain exceptions) take place in that district. If both parties have resided for fifteen days in different districts, the notice may be given to the superintendent registrar of either district, but the marriage must (with certain exceptions) take place in the district in which the notice was given.

On the request of the party who gave the notice, the superintendent registrar may issue his certificate and licence, provided that one clear day (excluding a Sunday, Good Friday or Christmas Day) has elapsed since he entered the notice in his marriage notice book. The marriage may then take place in the building specified in the notice at any time within three months from the day on which the notice was entered in the book.

4. Registration of Marriages.—A marriage in a church of the Church of England is registered by

the clergyman solemnising the marriage. A marriage in a Nonconformist church may be solemnised in the presence of an authorised person (*i.e.*, a person authorised by the trustees or governing body to be present at the solemnisation of marriages in that building), in which case the marriage is registered by that person, or in the presence of a registrar of marriages, who will register the marriage. A marriage according to the usages of the Society of Friends (Quakers) is registered by a registering officer of that Society; in the case of a Jewish marriage, registration is effected by the secretary (for marriages) of the synagogue to which the husband belongs. A marriage in a register office is registered by the registrar of marriages.

The particulars recorded include the date and place of the marriage, the names, ages, marital condition, and occupations of the parties, and the names and occupations of their respective fathers. The entry is signed by both parties to the marriage and two witnesses.

5. Marriage Fees.—(a) *Marriage According to the Rites of the Church of England.*—Generally, fees for a marriage after banns amount to £1 2*s.* if the parties live in the same parish or £1 12*s.* 6*d.* if in different parishes. Fees for a marriage on a superintendent registrar's certificate amount to £1 13*s.* if the parties live in the same registration district and £1 16*s.* if they live in different districts. Fees for a marriage by ecclesiastical licence amount to between £3 and £4. The fee payable for a special licence is £20.

(b) *After Civil Preliminaries.*—The following fees are payable in respect of the civil preliminaries to a marriage :—

	Superintendent Registrar's certificate.		Superintendent Registrar's certificate and licence.
	Notice in one district.	Notice in two districts.	
	s. *d.*	*s.* *d.*	£ *s.* *d.*
Entry of notice .	1 6	3 0	1 6
Superintendent Registrar's certificate	1 6	3 0	1 6
Superintendent Registrar's licence	—	—	2 5 0
Attendance of registrar of marriages (if required by law)	7 6	7 6	15 0
Total . . .	10 6	13 6	£3 3 0

In the case of a marriage in a registered building, however, further fees may be found to be payable to the Minister or the authorities of the building in regard to the solemnisation of the marriage. An additional fee will be payable if a marriage certificate is required.

6. Marriage Certificates.—Marriage certificates may be obtained from the person registering the marriage immediately after the ceremony for a fee of 3*s.* 9*d.* If application is made at a later date to the person having the custody of the register, a search fee will normally be payable in addition. Marriage certificates required for certain statutory purposes are obtainable from the person having the custody of the register at a special fee of 1*s.*

III. HOW TO BUY A HOUSE

1. INTRODUCTION.

The following guide has been compiled to help those who want to buy a house, especially young people founding a home. For many of us the need to buy a house comes but once in a lifetime; or, at any rate, so seldom that we have little experience to guide us. Many people, therefore, pick up such knowledge as they can at the last moment as they go along. That they tumble unawares into pitfalls is not therefore surprising. It is to save the house-seeker from those mistakes, which can be so costly and worrying to him, that the following guide is offered.

The guide has two main parts: first, how to make sure that the purchase is a sound one; and second, how to obtain the necessary funds. In addition, there is an explanation of the rates and income tax on a house and what reliefs can be obtained.

The advice may well seem more complicated, at first sight, than the newcomer to the problem expected. But when he reads it the main points will be found to be simple and clear, and the advice will repay careful study.

In addition to an explanation of how to select a house and get the money for it, information is offered on important subsidiary matters, such as how the purchaser may assure his family if he dies before a mortgage is paid in full. It is also explained how grants can be obtained for conversions and improvements.

The figures quoted in this section are those ruling at the time of going to press.

2. THE ESSENTIAL QUESTIONS TO ASK.

The Nature of the Property.—There are certain preliminary points which you need to get clear before entering into any commitments. You should think most carefully over the general position of the site; the nature of the soil; handiness to shops; what daily transport is available and what schools there are in the neighbourhood. You should ascertain the exact nature of what is being sold. Is the land leasehold or freehold? If it is leasehold, your ownership will be only for a stipulated number of years, often ninety-nine, sometimes more and sometimes much less; rent will be payable; and there are likely to be restrictions on its use. Though freehold usually means outright ownership of the land, freehold may also carry restrictions, such as debarment on use for business purposes or conversion into flats, or there may be limitations on the type of structure or size of house which can be built.

The Nature of the Neighbourhood.—Next comes essential information about the neighbourhood as a whole. Is it already zoned, or likely to be zoned, for industrial or other non-residential development? Are developments in hand, or possible, near enough to be inconvenient or liable to affect the amenities or value? The local Planning Authority (whose address you can find from the local council office) can usually give guidance on all these points. Equally essential is to find out if the land is subject to any rights of way, or other "easements" as they are legally termed.

Services and Roads.—Handiness to main drainage and gas, electricity and water supplies must be considered; installation may be costly, if any or all of these services have to be carried some distance. If roads have not been made up or adopted by the council, it should be found out when they will be built or adopted, where they will run, and the probable liability in road charges.

Local Bye-laws and Planning Clearance.—Assuming a clear bill up to this stage, local bye-laws and planning rules must be taken into account if a new house is to be built. Not any kind of building can be put up. It must conform to local standards of construction and safety. Its outward appearance and the facing materials used must also be approved by the local Planning Authority. An architect is the best adviser on these points. Once bought or built, owners cannot do anything they wish with houses. In addition to any restrictions going with the land, as mentioned above, the local Council and Planning Authority may have a definite say in all proposals. For example, their approval is necessary before a house can be converted to flats or for business purposes, or put to any other use.

The Need for a Surveyor and a Solicitor.—A qualified surveyor should be called in to report on

the condition and value of an existing house in which you are seriously interested. You will thereby know exactly what it is you are thinking of buying, and you will know within limits what you ought to pay. Various legal points must also be considered, and a solicitor should be consulted at the earliest stage of negotiation, to look after matters such as the title to the property, restrictions on use, conveyance and, a complicated matter calling for expert advice, the likelihood of the land being lost by compulsory purchase. On written application to the local council it must state whether, so far as it knows, the land is liable to compulsory purchase within five years.

The Golden Rule, is therefore: Obtain professional advice at the earliest stage—from a surveyor and a solicitor acting for you and independent of another party to the transaction. Where necessary, as, for example, when building a house, you should also consult an architect. The safe rule is not to enter into any commitment off your own bat. But if you do make any undertaking make sure that you introduce into your undertaking the words "subject to contract." Thus if you pay a deposit to a house agent as stakeholder state, in writing, that the payment is "subject to contract."

3. HOW TO BUDGET.

Stamps and Fees.—Sufficient money must be available to cover every need. You will, of course, remember that expenditure does not stop at the cost of the property itself. You will need to have money for stamp duties, legal charges, and expenses on the conveyance (or transfer) of the house if it is being bought, or on the land only if it is being built to plans; stamp duties, legal and inspection fees, and expenses in connection with the mortgage if money is being borrowed; and a fee for the surveyor who examines before purchase. All are payable by the purchaser. The actual amounts depend on the purchase price of the property or land and the amount of any mortgage advance. Stamp duty, payable to the Inland Revenue, as from August 1, 1958, is nil up to £3,500; ½ per cent. up to £4,500; 1 per cent. up to £5,250; 1½ per cent. up to £6,000; thereafter the full 2 per cent. Legal charges are at a set scale related to the purchase price. For example, if the land is unregistered the scale is 2½ per cent. on the first £1,000, 1½ per cent. on the next £2,000, and ¾ per cent. on the next £7,000. If the land is registered at H.M. Land Registry, fees are less, rates being 1½ per cent. on the first £1,000, 1 per cent. on the next £2,000, ½ per cent. on the following £1,000, and so on; but Land Registry fees will be payable at the rate of £3 15*s*. for the first £1,500 and 2*s*. 6*d*. for each extra £50 or part of £50.

Total Expense for the Conveyance.—A reasonable estimate of the maximum total expenses for *conveyance*, including incidental expenses and stamp duties, is, therefore, say, 2–2½ per cent. on the purchase price—less, of course, if the land is registered. Further, though smaller, sums will be payable if a mortgage has to be arranged. The whole set of expenses can add as much as 3–3½ per cent. to the outlay.

Other Monetary Needs may include: removal expenses; cost of fitting, curtains, and new carpets; structural alterations, decorating, etc.; new or additional furniture; and laying out a garden, including the cost of tools. The total will depend on circumstances and particularly whether you are moving to a new house or setting up home for the first time. The total amount can be substantial, and it is important that before entering into any commitments, you should draw up a budget of what capital you need; and if insufficient capital is available you should ascertain the amount which can be borrowed on mortgage. How to obtain a mortgage is explained in the next paragraphs.

4. HOW TO RAISE A MORTGAGE.

Who Lends Money?—Building Societies, Insurance Offices, and Local Authorities all lend money to enable people to own their homes. Banks also lend money and, subject to membership conditions, Trade Unions and Friendly Societies. While details may vary, some broad general rules apply to most methods. They are: (1) The property must be freehold or, if leasehold, must have a life of 20–30 years more than the repayment period of the mortgage. (2) The property must, in many instances, be constructed of brick, stone, or concrete—timber-built or half-timbered houses will not be entertained by some lenders. (3) The loan will be calculated on the value as decided by the lender's surveyor or the purchase price, whichever is the lower. (4) Normally, only a proportion of the price or value will be advanced, the amount usually depending on: (*a*) the age, condition, size, and situation of the house; (*b*) the lending policy of the mortgagee; and (*c*) the age, financial position, prospects, and family circumstances of the borrower. A useful general guide to (*c*) is that, in order to avoid taking on financial commitments which might become burdensome, mortgage repayments, rates, and a fair allowance for repairs should total not more than around one-quarter of the borrower's income.

How Much is Lent?—The percentage advanced varies widely, and depends partly on the method of borrowing. But a broad indication for freehold or long leasehold properties for owner-occupation costing not more than, say, £3,500–£4,500 is: new, up to 85 per cent.; reasonably modern older types, up to 80–85 per cent. On higher priced, large or pre-1918 houses the amount may be anything from 66⅔ to 75–80 per cent. Where the price is substantially below current market value, such as may happen if a rent-controlled house is being bought at a favourable figure by a sitting tenant, most lenders will advance a larger proportion; though, on the reasonable stipulation that the owner should have some cash stake in the property, probably not more than 95 per cent. of the cost. Likewise, as explained in later sections, larger loans may be made when suitable guarantees or additional security can be provided.

Loans for Houses Being Built.—Special considerations apply when building one's own house. Loans are not normally made on bare land; but if its purchase and commencement of building are a more or less continuous operation, an advance may be made on the land if its value is: (*a*) high in relation to the total cost of the completed property, and (*b*) more than the borrower will have to find himself. For example, if the land costs £750, building, etc., £2,250, and a loan of 80 per cent. will be made on the total of £3,000, a sum of £150 would be advanced on the land itself. In every case, however, the amount lent will be based on the surveyor's valuation of the completed property. This will take into account the cost of the land, building, and architect's fees, which latter are properly reflected in the value. It is possible in most cases to have the advance in up to three or four instalments as various stages of building are completed. Whatever the nature of the property, the borrower has to pay out of his own resources the costs of conveyance of the house or land, as mentioned earlier, plus legal and other charges in connection with the mortgage. As explained before, the two sets of expenses can add up to a further 3½ per cent. to the cash outlay.

Three Points for the Future.—Make sure when arranging the advance that lump sums can be paid off at any time, with a proportionate reduction in the interest payable. You can ask the Building Society if an extra loan will be possible should money be required at some future date to pay for additions, improvements, or heavy repairs. Finally, if for any reason whatever, it is difficult to keep up repayments, discuss the problem with the lender at the earliest stage—a temporary reduction in payments will probably be made to tide over the difficult period.

5. HOW A BUILDING SOCIETY HELPS.

The Need for Early Consultation.—Building Societies encourage prospective owners to discuss their propositions with them at the earliest moment. By finding out how much you can borrow you can be saved a lot of disappointment

and loss of money by way of deposits and survey fees.

Surveyor's Inspection.—Inspection of the property by the society's valuer is the first step after the preliminary discussion. A typical scale of fees is £2 on a purchase price up to £500, with additions of 10*s*. for every extra £250 up to £2,000 (at which level the fee is thus £5) and 4*s*. per £100 thereafter up to £10,000; plus travelling expenses over a certain distance. The valuer's report is confidential to the society, and is not available to the applicant. A decision to offer an advance is made normally within a day or two of the receipt of the report. In the case of new houses built to individual design preliminary arrangements and the offer of an advance are made on the basis of architects' plans and builders' estimates.

How Much Will Be Lent?—Societies, when a substantial loan is wanted, make the figure as large as possible commensurate with the security offered, the ability of the borrower to meet repayments, and their individual policy. Normal maximum amounts are 75–85 per cent. on reasonably modern and new properties costing up to £3,500–£4,500 and less on more expensive ones. Increased proportions may be arranged, however, if additional security is provided. Up to 95 per cent. may be considered if the borrower himself can provide extra security in the form of Trustee Securities, National Savings Certificates, another property, or a life-assurance policy with a sufficient surrender value. Up to 90–95 per cent. may also be arranged if a third party of financial substance will put up good security to cover part of the loan.

Guarantee Schemes.—Building Societies offer guarantee schemes in conjunction with insurance companies. One special plan provides for 90–95 per cent. advances to approved applicants on houses valued at not more than, say, £3,500–£4,500. A single insurance premium, which is usually added to the loan, is charged on the amount of the extra advance. There is also a Government–Local Council scheme for advances of up to 95 per cent. on new and *old* property.

Methods of Repayment.—Optional methods of repayment are offered by most Building Societies. The *Monthly Repayment* system is the most widely used and popular. Equal calendar (or lunar) monthly instalments paid throughout the term of the mortgage cover both interest and repayment of principal. Typical *calendar* monthly payments on each £100 borrowed for various periods and different interest rates are:

Number of Years	*Interest Rate*					
	5%		5½%		6%	
	s.	*d.*	*s.*	*d.*	*s.*	*d.*
5	38	6	39	1	39	7
10	21	7	22	2	22	8
15	16	1	16	8	17	2
20	13	5	14	0	14	7
25	11	10	12	6	13	1

While repayments can be arranged over any lesser number of years, the normal maximum is twenty to twenty-five, though some societies may arrange longer terms in particular circumstances. The advantage of this system is the even spread of the outgoings. In the early years the greater part of each payment represents interest, which, however, falls steadily as the load is reduced. The society usually reserves the right to increase—or reduce—the rate of interest on giving due notice. Increases are applied in ways giving the minimum inconvenience to the borrower, often by extending the repayment period.

6. HOW LOCAL COUNCILS AND BANKS HELP.

Local Authorities, including County Councils can, if they wish, advance money for home ownership under various Acts. Applications for details of mortgage facilities available for the area in which the property is situated should be made to the Treasurer or Clerk of the appropriate local Council. These facilities apply to property of any value and, though not always available, up to 100 per cent. may be lent. Interest is generally charged at ¼ per cent. above the rate at which the Council itself borrows from the Public Works Loan Board, which fixes its rates in accordance with money-market conditions and the term of repayment. The interest is, as a rule, fixed for the whole period of the loan, though some Councils have taken powers of variation. There is, of course, no life-insurance protection; but, as explained in the Life Assurance section, this may be arranged by taking out a reducing term, or mortgage protection, assurance.

Loans can be made by Local Authorities for the conversion of buildings into houses or flats and for the alteration, enlarging, repair or improvement of dwellings. (See paragraphs below on Improvement and Conversions.)

Bank Loans.—Banks are generally prepared to help within certain limits, the main considerations being that: (1) the borrower is an established customer of good standing; (2) the advance can be reduced steadily and repaid entirely over a relatively short period of, say, eight to ten years at the outside; and (3) no more than two-thirds to three-quarters of the value is to be lent, or additional security such as marketable investments, other property, or life assurances with surrender values can be put up. A bank loan is subject to half yearly or annual renewal, and may therefore have to be repaid on due notice, though this is given only in exceptional circumstances. Likewise, bank loans are subject to restrictions such as credit squeeze or Government financial policy.

Private Mortgages, up to two-thirds or three-quarters of the value, may also be obtained, mostly through mortgage brokers, solicitors, and estate agents. Interest may be ½ to 1 per cent. more than on building society advances. Repayment may be by instalments, but is more usually in one sum at the end of an agreed term, which calls for the accumulation of funds. This private field is often the best one for raising a second mortgage when it is impossible to obtain enough in the normal way on a first charge. Second mortgages, in view of the risk involved, generally have to be repaid over a comparatively short period of, say, two to three years and the interest ranges up to 7 or 8 per cent.

Bridging between One House and Another.—It may be necessary to bridge a gap between payment for the new house and receipt of the proceeds of sale of the old. If the present house is not mortgaged and no loan, or only a relatively small one, is needed on the new property, the bank may be able to help. If the present house is mortgaged, consult the lender. Arrange the financial side well before entering into any contracts or commitments on the new transaction. Established mortgage brokers and insurance brokers can be of help in the arrangement of mortgages, especially where it is desired to link the loan with endowment or mortgage protection assurance; or it is difficult to obtain the full amount required through the direct channels.

7. RATES.

Rates, levied by Local Authorities, are payable on all occupied house property—by the owner if he is also the occupier and often by the tenant if a house is rented. The amount depends on: (*a*) the rateable value, and (*b*) the rate in the £ levied by each Council. The latter varies widely Council by Council, and is liable to annual or even half-yearly change.

Rateable Value.—Under a comprehensive revaluation completed in 1955 all dwellings have been reassessed on a common basis laid down in the Valuation for Rating Act, 1953. The starting point is the *Gross Value*, which is the rent at which the property might reasonably have been

expected to let at end-June 1939, with: (*a*) the tenant paying all usual tenant's rates and taxes (but excluding income tax); and (*b*) the owner meeting the cost of repairs and insurance. A *Repairs Allowance* is next given at fixed scales. The net figure left is the RATEABLE VALUE, and it is the one on which rates are paid. The new values came into effect as from April 1st, 1956. Ratepayers may appeal for reductions in the gross value at any time during the currency of the rate. This right is particularly important when a new house is first valued. An appeal must first be made to the local Inland Revenue Valuer, whose address is obtainable from the town hall or council offices.

If the valuer's decision is unfavourable the appeal can be carried to the local Valuation Court. A final appeal can be made to the local Land Tribunal, which, however, may entail certain costs. A qualified rating valuer should be consulted in complicated cases.

8. INCOME TAX.

Net Annual Value.—Income Tax assessments on property, made separately by the local Commissioners of Income Tax, also start with a *Gross Value*, which can be defined as the fair rental value with the tenant paying rates and the owner repairs and insurance. (The income-tax figure, it should be noted, is not necessarily the same as the rating gross value.) A repairs allowance (automatically given) is based on the gross annual value, as under:—

G.A.V.	*Repairs Allowance*
Up to £40	One-quarter of the G.A.V.
£40–£50	£10.
£50–£100	One-fifth of the G.A.V.
Over £100	£20, plus one-sixth of the G.A.V. over £100.

The balance, known as the *Net Annual Value*, is the amount on which Schedule A, or Property Tax, is assessed.

Appeals.—An appeal for a reduction in the gross annual value can, as with rating valuations, be made by the owner at any time. When a new house is assessed for the first time an appeal must be made within forty-two days of receipt of the notice. All appeals should first be made to the local Inspector of Taxes and, if no satisfactory agreement can be reached, taken next to the local General Commissioners of Income Tax.

Relief for Repairs.—Rebates may be claimed for repairs when actual expenditure over specified periods exceeds the fixed allowance. The normal basis for making what is called a *Maintenance* (*or Excess Repairs*) *Claim* is the *average* spent over five consecutive years, generally ending March 31st. After making the initial claim, subsequent claims are made year after year by dropping out the expenditure for the earliest year and adding that for the newest, until the five-year average drops below the fixed allowance. One useful exception to this general rule may apply where a property has been owned for less than five years and a lot of money has been spent on it. If the previous owner's expenditure is known it can be included with such outlays to arrive at the five-year average. Alternatively, it may be possible to arrange with the Inspector of Taxes to work on actual yearly expenditure until a full five years' figures are available. All claims must be supported by receipted and detailed bills, which should always be kept. The cost of insuring the house—but not the contents—should be included. Money need not be spent each year; it is the five-year average which matters. Claims must be made *by the owner* within six years of the end of the relative tax year to the local Inspector of Taxes.

How the Owner Pays Income Tax.—When it comes to calculation of the income-tax liability on a house the net annual value is taken into account as part of the owner's income. Tax, if any, is then payable at the rate or rates applicable to the total income from all sources after deduction of personal and other allowances and reliefs. The owner obtains relief, in addition to any maintenance relief, in respect of the annual interest paid on a mortgage or loan on the security of the house. If the interest is paid to a building society, local council, certain insurance companies or a bank, relief will be given normally by setting off as much as possible against the assessment on the house and the balance, if any, against other income. But if the mortgage is the type where income tax is deducted from each interest payment such tax will have to be paid over to the tax collector and the assessment, or part of it, will remain. Though this seems to be a complicated way of doing things, the net effect is the same and full relief is given. All queries about property tax assessments should be addressed to the local Inspector of Taxes.

9. GRANTS FOR IMPROVEMENTS AND CONVERSIONS.

What Grants Cover.—Grants towards the cost of certain types of improvements and for conversions can be made to property owners by Local Authorities. *Improvement* for this purpose means work, other than ordinary repairs, necessary to bring a dwelling up to reasonable modern standards of convenience and comfort. Grants are now of two kinds. A *Standard* grant may be claimed *of right* to instal five amenities: bath or shower in bathroom; wash-hand basin; hot-water supply; water closet; satisfactory food storage—of up to one-half of the approved cost but subject to specified maximum payments. A *Discretionary* grant can be made for a much wider range of improvements, and for *conversions*, though qualification for assistance is decided solely by the Council and the cost of approved work must exceed £100; up to one-half may be granted, with a maximum of £400 for each dwelling. *Conversion* work includes the division of a suitable house or group of houses into flats or other self-contained dwellings.

Conditions of Grant.—To qualify for a grant council approval must be obtained *before* any work is started. The property must be brought up to certain defined standards and usable life. Fees for professional help and advice may be included in the approved cost.

10. PROTECTION OF DEPENDANTS AND HOME BY ASSURANCE.

Freedom from Debt in Case of Death.—Life assurance can be linked with house purchase in various ways to provide not only finance, but protection for dependants and, perhaps, a fund for meeting major expenditure some way ahead. A popular method is a loan from a life insurance office repayable by means of an endowment assurance. It is a two-way transaction. The insurance office makes a fixed loan for an agreed number of years. Simultaneously, the borrower takes out an endowment assurance for at least the same amount and the same period. Thus—which is the great merit of this method—if he dies at any time after paying the first premium the endowment pays off the mortgage and leaves the house free of debt. The maximum maturity period of the endowment assurance is normally twenty to twenty-five years or age sixty-five, whichever is the shorter term.

Home Protection Insurance.—A growingly popular and cheaper method of "insuring" reducing types of loan is, however, a reducing-term insurance, more popularly called "mortgage protection," "home protection" insurance, and so on. Though a number of variations are available, the basis is similar—the amount assured falls annually as the mortgage is reduced. Under the simplest form the insurance provides enough to repay the balance of the mortgage if death occurs before its complete repayment, but the borrower obtains no cash benefit if he lives to the end of the term. Premiums, payable for only a limited number of years, vary according to the age of the borrower and rates for younger age groups are no more than a few pounds per £1,000 original loan. The need to insure your house and contents is explained in Part IV.

IV. A GUIDE TO INSURANCE

It is simple prudence to secure the benefits of insurance. You should ask yourself not whether you ought to insure but which pattern of insurance suits you best. Life assurance will give you confidence and your dependants too; and this will promote that trust which makes for happy relationship. Moreover, life assurance is a form of systematic saving against the inevitable rainy day. And there is a special word of advice for women, who are naturally especially concerned about financial security.

The figures quoted are those ruling at the time of going to press.

Life Assurance: Who may Insure.—You may insure your life and thus provide for your family in the event of your early death. A husband may take out an insurance on the life of his wife, and vice versa. It is a condition of the grant of a life policy that the person effecting it should have an interest in the life to be insured, known as an insurable interest. Every adult person has an unlimited insurable interest in his or her own life. A husband has an unlimited insurable interest in the life of his wife, and vice versa. These are, however, exceptions to the general rule, which is that the interest must be pecuniary, *i.e.*, measurable in terms of money. Relationship in itself does not constitute an insurable interest. Thus a parent as such has no insurable interest in the life of his child, nor a child in the life of its parents. It is to be noted that provided the insurable interest subsists at the time the policy is effected, the interest may be reduced or disappear entirely during the term of the policy without invalidating the contract.

"With" and "Without Profit" Assurance.—Both whole-life and endowment assurances can be obtained either with or without the right to participate in profits, termed bonuses, a larger premium being charged for participation. A policy-holder's share in the profits is usually added to the sum assured. It is known as a reversionary bonus, and is payable with the original sum assured at the time of claim. These bonuses may, if desired, be surrendered for immediate cash without disturbing the original assurance, but the cash value, is, of course, considerably less than its reversionary value as an addition to the sum assured. The bonus may be calculated as a "simple" bonus on the sum assured or as "compound" bonus on the sum assured and any bonuses already added.

Whole Life Assurance.—The first contract should provide life assurance for as long as it can possibly be needed, which generally means a whole of life policy. The premiums may be payable throughout the lifetime of the assured, or can be limited to a fixed term of years, when, if the life assured survives beyond the fixed term, the policy continues in force without further payments of premiums. A whole-life policy under which premiums are payable throughout the life of the assured, and which does not participate in profits, is the cheapest form of permanent life assurance because it provides the maximum sum assured with the minimum premium outlay. A whole-life policy, either with or without profits, and preferably with premium payments ceasing not later than retirement age, should form the backing of every well-planned scheme of life assurance. At age 25 a whole-life "without profit" policy for £1,000 will cost around £15 a year subject to rebate of income tax, or, say, £17 a year if it be arranged for premiums to cease at age 65. If effected on the "with profit" plan, a whole-life policy for £1,000 with premiums payable throughout life will cost about £22 at age 25, or around £24 a year if premium payments cease at age 65.

Endowment Assurance.—In its simplest form an endowment assurance secures a stipulated sum upon the survivance of the life assured to a stated date, or upon his death should that occur earlier. The most important advantage of endowment assurance is provision for old age. Where adequate assurance has already been effected as a provision for dependants, a short-term endowment assurance is often the best means of making provision for school expenses or providing a child with a start in life. But apart from special circumstances of that kind, the best form of endowment assurance in the great majority of cases is a policy maturing at the prospective age of retirement. Many men, of course, come under a pension scheme, but the pension will by no means equal their earnings, and may die with them. Their wives may enjoy the protection of a widow's pension, but this is likely to be a modest amount and perhaps inadequate, even allowing for an amount under the National Insurance scheme. There is therefore no better object for your savings than an endowment assurance maturing at 65. It provides a reasonable amount for dependants in the event of early death, while if the assured survives to 65 he receives a capital sum, when he can convert the policy moneys into a pension for himself, or himself and his wife.

Endowments by Instalments.—The proceeds of an endowment assurance may be payable by instalments over a period of, say, 5, 10, or 15 years free of income tax. The person assured would, of course, have an option to take a lump-sum payment at maturity instead of payment by instalments, and his representatives could make such a choice in the event of his death during the policy term.

Optional Endowments.—An option to convert to an endowment assurance can always be attached to a whole-life policy, so that if at the end of, say, five or ten years an endowment would better suit the assured's needs, the change can then be made. The option is with the assured, and if ill-health has overtaken him since effecting the whole-life assurance, he will no doubt prefer to retain the cheaper form of policy. This freedom of choice is of great value whether the policy is intended as a complete provision in itself or whether it is to be used in combination with other policies.

"Income" for Dependants.—The "family-income" type of policy has been devised because it is when the family is young that it needs the most support. There is a plan to suit every need and every purse. Although some offices assure "income" independently of "capital" provision, the most beneficial plan is where the income benefits form part of a whole-life or long-term endowment assurance, to which the income benefits may be added at any time. At age 30 next birthday, an annual premium around £22 payable during the first 20 years and then reducing to around £17 will provide, in the event of death of the assured within 20 years, a tax-free payment of £150 per annum by monthly instalments for the remainder of that period, and, in addition, a cash sum of £1,000 at the end of the income benefit period. If death occurs after 20 years from the commencement of the policy, a cash payment of £1,000 is made at death. There are various varieties of this principle.

Financial Security for Women.—An increasing number of women are effecting policies, both as provision in the event of death as well as for old age. The woman following a career can provide for retirement at 55, or, at the latest 60, by an endowment assurance, or by what is known as a double-endowment assurance, or by the purchase of a deferred annuity. The two former have the advantage of tax rebate not allowable on premiums under a deferred-annuity contract. For a young women the problem is: "If I marry, a policy on my husband's life is important. If I do not marry, a pension for myself is necessary." For this situation a number of special assurance schemes have been devised. Under one such scheme a single woman assures her own life for a sum payable, either with or without bonus additions, at 55 or 60, and has the option, should she marry, to exchange the assurance for one on the life of her husband. By another, she has the option on marriage to take a small cash payment and, subject to her husband's not having reached 45, can exchange the policy for an assurance on her husband's life. In both cases the substituted policy remains for her absolute benefit, and is

issued without medical examination of the husband or other evidence of his health.

Retirement Annuities.—A self-employed person, or an employee not in pensionable employment, may under the provisions of the 1956 Finance Act effect an "approved" deferred annuity to provide a pension commencing not later than at age 70 and not earlier than age 60, and obtain full tax relief on the annual premiums paid. The benefit, however, must be in the form of a pension and, excepting a possible return of premiums at death before retirement, no cash payment is provided. The annuity acquires no loan or surrender value, and does not of itself provide adequately for dependants. By reason of these limitations an endowment assurance as previously outlined is in many cases the more suitable choice.

Assurances for Children.—The cost of education can be met by an endowment assurance on the life of the parent or guardian. There are special assurances available with the sum assured payable at *termly* intervals over a period of years. In the event of premature death of the parent or guardian premiums cease at once, and the education fees provided for would then commence, or, alternatively, fees of the original period of the assurance. The ordinary rebate of income tax can be claimed on the premiums of these policies.

Child's Deferred Assurance.—A popular form of policy for the benefit of a child on reaching maturity is the child's deferred assurance, which becomes the property of the child on becoming 21 or 25, when a number of valuable options may be exercised. The most valuable option permits the assurance to be continued on a whole-life or endowment basis—with or without profits—at the same low premium, irrespective of the state of health of the child at that time, and without regard to occupation, travel, or foreign residence. The policy may thus be said to provide insurance against uninsurability, and this possibility is a very real one. The policy sometimes carries a special educational option at, say, 15, to meet school fees. Varying schemes of this nature are offered at comparatively small premiums, often no more than £10 per annum, or £1 per month. A small extra premium, which varies with the age of the parent, will provide that, if the parent dies, all premiums cease up to the option age. No loss can be sustained under this class of assurance, for all premiums paid are returned should the child not survive to the agreed "option age."

Life Assurance and House Purchase.—No man should buy a house on mortgage without making sure that, in the event of his death before the mortgage has been paid off, his wife and family will be free from any liability in connection therewith. The only way to safeguard one's dependants is through life assurance, and particularly by means of a life policy specially adapted to the purpose. Enquiry should be made as to the various kinds of assurance for this purpose.

Loan, Surrender, and Paid-up Values.—Both whole-life and endowment assurances acquire a surrender value after a minimum number of annual premiums (usually two or three) have been paid. Alternatively, either type of contract can be converted into a paid-up policy, *i.e.*, the payment of future premiums is dispensed with, but, of course, a reduction is made in the sum assured. The surrender value of a whole-life or endowment assurance increases as time passes, and provided that premiums are regularly paid, policies form good security for a loan either from the office itself or from a bank. This may prove very valuable in the event of temporary financial embarrassment. Policies acquiring a surrender value are in general subject to special conditions of considerable value to the policy-holder in the event of premiums not being paid when due. Under what are termed "non-forfeiture regulations" the accrued surrender value is applied automatically to keep the assurance in force. The non-forfeiture period lasts so long as there is a surrender value sufficient to cover the unpaid premiums.

Income-tax Allowance.—Under existing legislation relief of income tax may be claimed on the amount of the premiums paid for life assurance effected by a person on his own life or on the life of his wife subject to the following conditions:

1. The amount on which relief is allowed is not to exceed one-sixth of the total income.
2. No allowance will be made in respect of that portion of any annual premium which is greater than £7 for each £100 assured if the annual premiums are £25 or more.

Subject to the above conditions, an allowance of income tax is granted as under, calculated at the highest rate of tax paid, *i.e.*, 2*s.* 3*d.*, 4*s.* 9*d.*, 6*s.* 9*d.*, or 8*s.* 6*d.* in the £ (in border-line cases the allowances will be partly at one rate and partly at another):

(*a*) When premiums eligible for relief do not exceed £10 annually, tax allowance is made on the actual premiums paid.

(*b*) When premiums exceed £10 but do not exceed £25 annually, tax allowance is made on £10 only.

(*c*) When premiums exceed £25 a year, tax allowance is based on two-fifths of the premiums paid.

Fire—Burglary—Accident—Personal Liability.—The householder can incur heavy losses through fire, burglary, storm, flood, and burst pipes, or maybe Common Law liability to servants or temporary and occasional employees about the house, or, as owner or occupier, to members of the general public. The householder should therefore effect an insurance on both building and contents against these and other risks under an appropriate comprehensive policy. A comprehensive policy—whether on buildings or contents or on both—gives a wider cover and is cheaper than separate policies. A liability with the possibility of heavy loss is that of a house-owner to the public arising out of accidents resulting in bodily injury or damage to property, for which the comprehensive insurance grants indemnity up to £25,000, with costs and expenses incurred additional. The normal comprehensive rate is 2*s.* 3*d.* per cent. on the full value of the building and 5*s.* per cent. on the value of contents.

Accident and Sickness Insurance.—Accidents mean lost earnings during incapacity, and often even in these days of the Welfare State, medical and surgical expenses. Personal accident and sickness insurance is therefore of undoubted value. Various schemes are available with premiums ranging from, say, £2 a year, according to the cover granted and the occupation of the proposer. The main types of cover are:

(*a*) an accidents only policy;
(*b*) an accidents and specified diseases policy;
(*c*) an accidents and all-sickness policy;
(*d*) a permanent sickness and accident policy.

These schemes are year-to-year contracts, renewal each year being at the option of the company. A permanent non-cancellable sickness and all-accident policy is available under which the company guarantees continuous cover to a given age whatever the sickness record may be. A permanent contract of this nature is particularly suited to the professional or business man, who, whilst able to command a substantial income so long as he is physically fit, would suffer considerable loss of earning power, and perhaps complete loss of income, in the event of a prolonged breakdown in health. The non-cancellable form requires a somewhat higher premium than the year-to-year contract, and is only issued by certain specialist companies after the proposer has been proved in good health by medical examination.

Personal Liability.—In daily life individuals may incur legal liability in many circumstances. If the individual is negligent, and through his negligence some other person suffers injury or damage to property, the negligent party may be responsible and have to make redress. Instances of this nature have increased considerably in recent years. Even where negligence is not proved, the cost and worry of defending a claim is something to be avoided by the layman. The proposal form of personal liability insurance is very simple, often requiring no more than the name, address, and signature of the proposer.

Cookery

By Good Housekeeping Institute

I. COOKING EQUIPMENT

Soundly constructed and well-designed cooking-utensils add immeasurably to the pleasure and ease of cooking. Careful and selective buying is well worth the trouble, and should result in a well-equipped cupboard that does not require constant replacements. The following points are among those to be observed :

1. Good cooking-utensils should be easy to clean. Look for a smooth interior, but avoid one that is too highly polished, as foods tend to stick and burn on an excessively high finish. Lids should fit well and be free from crevices.
2. Examine the handles to see that they are firmly fixed and sufficiently insulated to stay cool when in use.
3. Sharp angles where the base and sides meet are to be avoided, as they make cleaning difficult.
4. For cooking on solid electric or other flat hot plates utensils must have a reasonably heavy machined base to ensure quick transfer of heat and eliminate waste. For non-solid plates thinner gauge pans are suitable, though too lightly made ones should be avoided, as they soon tend to lose their shape.
5. Avoid buying unnecessary gadgets without being certain of their ultimate usefulness. They should be easy to store and clean, and should be simple and effective to use.

SPECIALISED COOKING-UTENSILS

Pressure Cookers.—These are becoming increasingly popular, largely because of the time and fuel they save. Pressure cookers are specially constructed pans, usually of aluminium, with a special fitting lid, a pressure weight, or spring-loaded valve, and some type of safety device. The modern pan type is reasonably light and simple to handle. Manufacturers' instructions for cooking must be followed closely, and when buying a cooker the choice should lie between those of reliable manufacture which have passed standard tests. The size should be chosen according to the number in family, and the cooker must have a base suitable for the type of hot-plate or burner on which it will be used.

Steamers.—For large households the tiered steamer is a most useful item of kitchen equipment. As a rule there are three separate pans which fit on top of each other over a base pan. One or more tiers can be used at a time, and the steam to each compartment can be separately controlled. Aluminium is the most suitable metal for this type of pan, and the handles and knobs should, of course, be insulated.

A simpler steamer, for small households, is a pan with a perforated base designed to fit over another saucepan. These are usually aluminium or enamel, and should have a well-fitting lid.

Preserving-pan.—Fairly heavy gauge aluminium is a good choice for a preserving-pan. It should have a fairly wide top to allow for the necessary evaporation during jam-making. The handles must be sturdy. Tinned copper pans are also satisfactory. Unlined brass and copper pans are suitable for jam-making only, and must be avoided for pickles and chutney, as vinegar reacts with them to form traces of a poisonous salt.

Electric Mixers.—A good electric mixer can save considerable time and energy, especially in large households. A reliable machine that is easy to operate and simple to adjust is essential.

Most electric mixers are primarily designed for making cakes and puddings, and for all whisking processes. Some have attachments for mincing, coffee-grinding, grating, blending, liquidising, juice extracting, dough-making, potato peeling, etc. Success in using a mixer depends largely on the careful following of directions. Best use can be obtained from a mixer if it has a permanent position in the kitchen where it can always be ready for use.

Knives.—It is really essential to have a good set of cooking-knives—

Vegetable Knife.—A small pointed knife with a blade 3 to 4 inches long. Some types have a serrated edge, and these are useful for slicing purposes.

Cook's or French Knife.—This knife is used for cutting up and chopping food, and has either a long or medium blade tapering to a sharp point.

Round-ended Knife.—A general-purpose tool.

Carving-Knife.—There are various different shapes and sizes of carving-knives. For ordinary joints a knife with a long and fairly broad blade, slightly curved and sharply pointed, is satisfactory. For game and poultry, a pointed knife with a shorter blade is necessary. For ham, tongue, etc., a long, thin, even-bladed knife without a pointed end is usually preferred.

CARE OF COOKING UTENSILS

Aluminium Saucepans.—Wash in hot water using a stiff brush. Avoid using scratchy abrasives and soda, even if the pan is discoloured This typical discoloration is quite harmless, and is due to traces of iron in the water or commercial metal. It can be removed, if desired, by boiling water with a weak acid, such as vinegar or fruit parings, in the saucepan. The outside of aluminium pans can be polished with fine dry steel wool.

Baking-tins.—Wash in hot soapy water, rinse and dry in a warm oven, or on the rack of a closed stove. Discoloured greasy tins should be stewed for an hour in water to which soda has been added in the proportion of 1 oz. to 1 gallon.

Casseroles.—Steep earthenware casseroles in cold water and then wash in hot soapy water, using a stiff brush.

Enamel Ware.—Soak immediately in cold water, and clean in hot soapy water. Salt can be used to remove any stains, but scratchy abrasives must be avoided, as they damage the surface.

Frying and Omelet Pans.—Pour off any grease and wipe the pan with a pad of absorbent paper. Wash only occasionally. New pans which are inclined to stick should be heated with a little fat. Remove from the heat and add a handful of salt. Wipe round vigorously with an old cloth or paper. Do not repeat this treatment too often, or the surface of the pan will be damaged.

Glass Ovenware.—Soak in cold water. Wash in hot water and soapless detergent, using a pad of fine steel wool or a cloth dipped in borax to remove any obstinate stains. Rinse well.

Kettles.—In hard-water districts kettles need to be defurred occasionally. Pour in a little vinegar, heat slightly, and leave to stand for an hour or two, when it will be easy to remove the fur. Rinse very thoroughly before using again.

Mincer.—Take to pieces and remove all scraps of food, using a skewer if necessary. Wash in hot, soapy water, rinse and leave in a warm place to dry thoroughly. Reassemble before putting away.

EQUIPMENT REQUIREMENTS

The following is a comprehensive list of cooking-utensils sufficient for two people setting up house. Those considered essential are marked with an asterisk.

Saucepans and Kettles, etc.

*6 saucepans (assorted sizes : 2 large, 2 medium, and 2 small)
Double boiler
3-tiered steamer
*1 shallow frying-pan
Deep-fat pan and basket
*2 kettles (1 large, 1 small)
Pressure saucepan or cooker (optional)

Baking-tins, etc.

- *12 patty pans (or 2 sets bun tins)
- 2 sandwich tins
- 2 pie plates
- *Baking-sheets
- Swiss-roll tin
- Flan ring
- *Set of pastry cutters
- *3–4 cake tins (assorted sizes)
- 2 wire cake-trays
- *Meat tin
- *Trivet for meat

Utensils for Food Preparation

- *Colander
- *Whisk
- Grater and shredder
- Potato masher
- *Pointed strainer
- Lemon squeezer
- Funnel
- *Pastry Board
- *Rolling-pin
- *Flour dredger
- *Pastry brush
- Salad shaker
- *Fish slice
- *Graduated measure
- *¼-, ½-, and 1-pint measures or one graduated measure
- Standard measuring-cups and spoons
- *Mincer
- Hair sieve
- Wire sieve
- *Chopping-board
- Vegetable and icing forcing pipes

Cutlery and Small Tools

- *Set of kitchen knives (round-edged, cook's, vegetable, palette, and saw-edged)
- *3 or 4 forks (large, small, and two-pronged)
- *2 or 3 wooden spoons (assorted sizes)
- *Kitchen spoons (cook's, perforated, scoop)
- *Potato-peeler
- Apple-corer
- Bottle-opener
- Tin-opener
- *Kitchen scissors
- *Knife-sharpener

China, Heatproof Ware or Enamel

- *Mixing bowl
- *4 pudding basins (assorted sizes)
- *2 or 3 pie dishes (assorted sizes)
- *2 or 3 casseroles (1 will suffice at first)
- *3 or 4 plates
- *3 or 4 jugs
- 1 soufflé case
- *2 jelly moulds (1 will suffice at first)

Other Equipment

- *Kitchen scales
- *Store jars and containers
- *Bread bin
- Sugar thermometer
- *Flour bin
- *Cake and biscuit tins
- Preserving-pan
- Small refuse bin

II. BASIC COOKERY METHODS

BAKING

This is a method of cooking foods by dry heat in the oven. It is a suitable way of cooking many foods, and nutritive loss other than that of Vitamin C is low. Times and temperatures, of course, require to be regulated according to the type of food.

Vegetables

Not all vegetables bake satisfactorily, as a moist heat is often required to soften the cellulose. The following, however, bake well, although (with the exception of potatoes) it is necessary to add a little fat, milk, or water to provide some moisture—potatoes, carrots, parsnips, turnips, Jerusalem artichokes, onions, and marrow. Beetroot bake extremely well when placed in a greased casserole and cooked until tender at about 300° F. Peel and serve hot or cold, either sliced or diced.

Times for Baking Vegetables.—*Potatoes.*—¾–1½ hours, according to size.

Artichokes and Parsnips.—1 hour.

Onions.—¾–1 hour.

Beetroots.—1–2 hours.

Macedoine in Stock.—¾-1 hour.

Fruit

Most fruits can be baked very successfully, with the addition of a little water to prevent shrivelling. Cook slowly in a covered dish, and at the start of cooking add sugar to taste.

Meat

Meat baked in the oven is usually referred to as roasted (S6 (2)).

Fish

This is a very suitable way of cooking fish. The fish should be weighed and wiped, and then placed in a greased fireproof dish. Sprinkle with salt, pepper, a little lemon juice, and then add a little milk or water. Dab with shavings of butter or margarine and cover with greaseproof paper.

The temperature required for baking fish is about 400° F. Allow 6–10 minutes to the pound and 6–10 minutes over, according to the thickness. Thin fillets take about 15 minutes. When the fish is cooked the flesh will appear white and firm, and will come away easily from the bone. A curd forms between the bone and the flesh.

Whole fish or round cutlets such as hake or cod can be stuffed before baking. The stuffing is placed in a cavity where the entrails have been removed. In the case of whole fish, the scales and eyes should be removed, but the head left. For plaice, sole, etc., using a sharp knife cut the flesh right down the back bone and loosen it away from the bone as far as the fin. Place the stuffing in the cavity.

A suitable stuffing is forcemeat (S23 (1)). Garnish with tomato, lemon slices, fennel, olives, or grapes, serve with parsley, fennel, egg, or anchovy sauce.

Cakes and Pastry

These are practically always cooked by baking. Times vary according to type and size of cake or pastry involved. It is important not to disturb cakes or pastry by opening the oven door too often while cooking. The following table will serve as a general baking guide :

Cakes, etc.	Temperature.	Time.
Plain Cakes :		
Small (*e.g.*, Rock Cakes) .	Hot (450–475° F.)	10–15 minutes
Large	Moderately hot (400° F.) lowering to Moderate (350° F.)	Approx. 1 hour per 1 lb. of mixture (varying with depth of tin)
Rich Cakes :		
Small (*e.g.*, Queen Cakes).	Moderately hot (400° F.)	15–20 minutes
Sandwich Cake . . .	Moderately hot (375° F.)	30–40 minutes (depending on depth)
Large (*e.g.*, Madeira) . .	Moderate (350–375° F.)	Approx. 1 hour per 1 lb. (varying with depth of tin)
Large (*e.g.*, Fruit) . . .	Moderate (325–350° F.)	1–1½ hours per 1 lb. of mixture (according to amount of fruit)
Scones	Very hot (475° F.)	8–10 minutes
Biscuits	Moderately hot (400° F.)	15–20 minutes

TEMPERATURES AND TIMES FOR BAKING PASTRY

Type of pastry and dish.	Temperature.	Time.
Shortcrust:		
Fruit pies	425–475° F.	35–40 minutes
Jam tarts	450–500° F.	10–15 minutes
Cornish pasties (with cooked meat)	450–500° F.	30–40 minutes
Flaky Pastry:		
Meat pies (with cooked filling)	425–475° F.	30–40 minutes
Patties	475–500° F.	10–20 minutes
Puff and Rough Puff:		
Flan cases	475–500° F.	10–20 minutes
Choux Pastry:		
Eclairs	450–475° F.	30–40 minutes
Potato Pastry:		
Vegetable pies	450–500° F.	30–40 minutes
Hot-water Crust:		
Pork pies	350–400° F.	1 hour
Suet Pastry:		
Jam roll	350–400° F.	1–1½ hours

For recipes and methods of making each see S23–26.

BOILING

The essence of boiling is the immersion of food in boiling water, and it is the simplest process in all cookery. In actual fact many so-called boiled foods are cooked at slightly below boiling point (212° F.) and are, therefore, strictly speaking stewed or simmered.

Boiled Meat and Poultry

Weigh the joint, wash or wipe it, and then tie or truss it according to type. Plunge into boiling salted water, having just sufficient water to cover the joint. Boil rapidly for about 5 minutes, and then reduce the heat and maintain the water at simmering point until the meat is cooked.

The preliminary fast boiling coagulates and sets the proteins so that a casing is formed, and the flavour and some of the juices are retained in the joint. Fast boiling must not be prolonged over the five minutes, or shrinkage and toughness will result. Simmering temperature is indicated by gentle bubbles rising up the side of the pan.

Vegetables and herbs can be added to the water for flavour. Salt meat should be soaked for several hours before cooking. Place it in cold water and bring slowly to the boil, skim and simmer the required time. Ham and bacon which is to be served cold should be cooled in the liquor.

Joints of Meat Suitable for Boiling.—*Beef.*—Brisket (fresh or salted), silverside (salted), flank, ox tongue.

Pork.—Leg, loin, best end of neck, belly (salted), hand and spring, head (fresh or salted), tongue and brains.

Lamb or Mutton.—Leg, breast, tongue, brains.

Veal, Calves' feet.

Ham and Bacon.

Fowls.

Times for Cooking.—For fresh meats allow 20 minutes to the lb. and 20 minutes over; for salt meats allow 25 minutes to the lb. and 25 minutes over.

A young fowl should be boiled for ¾ hour, and an old one for 2–3 hours.

Cooking Times for Tongues.—Sheep's tongues, 1½–2 hours; calves' tongues, 1½–2 hours; ox tongue, 4½–6 hours; ox tongue (pickled), 2½–3 hours.

Boiled Fish

This method is suitable for large whole fish, or thick cuts of white fish or salmon. Small fish are better steamed.

To prepare a whole fish, wash quickly in cold water, remove the guts, scales, fins, and eyes, and rub off any black skin from the inside of the fish, using a little salt. Thick cuts of fish only need wiping or scaling. Have sufficient water in the pan to cover the fish, and add a teaspoonful of salt to each quart of water, or for white fish a teaspoonful of vinegar. Draw the pan off the heat, place the fish in the water, and cook very gently for the required time. As fish is very tender and breaks easily, it is best to cook it at just under simmering point.

Times for Cooking.—For a large fish allow 10 minutes to the pound and 10 minutes over. Cook small fish until the flesh is firm and will leave the bone quite clean (10–15 minutes).

Vegetables

Boiling is a very satisfactory way of cooking vegetables, as it softens the cellulose, but in order to retain the maximum amount of nutriment the "conservative" method should be followed. Allow sufficient water to just cover the vegetables —for green vegetables approximately ½ pint water to 1 lb. greens. Add salt in the proportion of 1 teaspoonful to 1 pint water. Bring the water to the boil, and retaining boiling point throughout, add the vegetables a handful at a time. The outside leaves of green vegetables should be added first, followed by the medium green ones, and lastly the heart. Place a well-fitting lid on the pan to prevent steam escaping, and shake two or three times during cooking.

Times for Cooking.—*Green Vegetables.*—Shredded, 7–10 minutes; brussels sprouts, 10–15 minutes; spinach, 15–20 minutes; peas, 10–15 minutes; beans, 20–30 minutes; beans (runner), 15–20 minutes.

Root Vegetables.—Diced, 20–25 minutes; sliced, 30–35 minutes; quartered, 30 minutes or more, according to age.

Puddings

With the exception of suet puddings, it is more satisfactory to steam, rather than boil, puddings. Boiled puddings tend to become waterlogged. A suet pudding should be wrapped in a scalded cloth which has been well floured on the inside. Place the pudding in rapidly boiling water, and keep boiling gently for the required time.

Time to Allow.—A meat or fruit pudding for 4 people, *i.e.*, ½ lb. flour, will take about 2 hours.

Cereals and Pulses

Oatmeal, rice and macaroni, pulses such as peas, beans, and lentils all boil well.

Oatmeal Porridge.—Bring 1 pint water to boiling point, and sprinkle in 2 tablespoonfuls medium oatmeal, stirring well. Continue to stir until boiling point is again reached, and boil for a few minutes, then allow to simmer, in a double saucepan if possible, for ½–2 hours, according to the size of the grains, until the oatmeal is well swollen and tender. More boiling water may be added if necessary, to make the porridge of a good pouring consistency. Salt to taste.

Commercially prepared oats or rolled oats can be cooked very quickly, according to the directions on the packet.

Rice (To Serve as a Vegetable or Garnish).—Allow about 2 oz. rice for each person. Wash thoroughly and put into a pan with plenty of boiling salted water. Boil rapidly without a lid for 15–20 minutes, until the grains are tender but not crushed. During boiling the grains of rice should dance about in the water. Drain the rice through a sieve, saving the water for soups, then hold under the running cold tap to rinse the rice thoroughly. Spread the rice on a cloth, turn the edges over and keep in a warm place to heat through and dry off. At intervals fork the rice, so that every grain is dry and separate.

Macaroni.—Allow a quart of salted water to 4 oz. macaroni. Place the macaroni in fast-boiling water and boil rapidly, stirring occasionally to prevent sticking, for 20–30 minutes. Some proprietary brands cook quicker—see directions on packet.

Pulses (Dried Peas, Beans, and Lentils).—Soak for 12–24 hours in warm water, with a good pinch of bicarbonate of soda. Place the pulses in a pan of fresh salted water, and simmer for 2–3 hours, or until tender; lentils take only ½–1 hour.

GRILLING

Grilling is one of the simplest and quickest methods of cooking. The grill should be well heated before use. The heat can be adjusted during the cooking by raising or lowering the grill pan. This can be done either by an adjustment in the pan itself or in the fitting in which it slides. Failing either of these facilities, raise it by placing a suitable tin under the pan.

Re-heating Foods under the Grill.—When serving vegetables *au gratin* or similar dishes, heat the vegetables in the sauce in a pan, and then empty into a hot fireproof dish, choosing a shallow one if possible. Sprinkle the top with grated cheese, breadcrumbs, etc., and immediately place under the grill, keeping the surface of the food directly under the heat until evenly brown. The dish should be fairly close to the heat, and it may be necessary to raise your grill pan by putting a tin or plate under it.

Choice of Meat.—Only tender and juicy cuts of meat are suitable for grilling, and the piece of meat you choose must be well hung, otherwise it will be tough and stringy when cooked. Fresh, underhung meat will never grill satisfactorily. Rump and fillet steak, chump chops, cutlets, tender liver, and kidneys, all make delicious grills.

Preparation and Cooking.—Wipe the meat with a damp cloth, cut steak into portions if necessary, leaving where possible a rim of fat; remove the spinal cord from chops; wash and wipe liver and kidneys, cutting them in half and removing the core. Brush all meat with oil or melted fat before placing on hot grid.

The heat should be intense to begin with, so have the grill red-hot. Place the meat on the greased grid and heat quickly, so that the surface juices coagulate and form a skin, keeping in the flavour and goodness. Allow about two minutes for the "sealing," until the meat has changed colour. As soon as one side of the meat has been sealed, turn and treat the other side in the same way. Do not wait too long, or the surface will become hard and overcooked. Thick chops or steaks require 10–15 minutes, and during this time they should be turned four or five times. Turn the meat with two spoons, taking care not to pierce the flesh, or the juice will run out.

Choice of Fish.—Herrings, mullet, mackerel, cod and salmon cutlets, plaice and soles, are all suitable for grilling.

Preparation.—Wash whole fish, remove scales, score with a sharp knife in three or four places, and brush with melted fat. Place on the hot greased grid and cook rather slowly, so that the fish is thoroughly cooked without any fear of burning. Turn once or twice, but handle the fish very carefully, as the flesh breaks easily. Insert the back of the knife next to the bone to see when the fish is cooked. Serve with lemon-juice and chopped parsley sprinkled over the fish.

Cutlets of Fish.—Tie the cutlets, to keep them a good shape; brush with fat, place on the greased grid and grill on both sides until the fish is cooked —about 10 minutes. Salmon cutlets are grilled in the same way.

Grilled Bacon or Ham.—Place the rashers or ham on the grid, place under the grill and cook for two or three minutes, or longer if the rashers are thick. As soon as the fat is transparent on one side, turn and cook on the other side. If eggs are cooked in the grill pan, the grid should be removed and the egg broken carefully into the fat and cooked until set.

Sausages.—Prick sausages, arrange on the grid, and place under the grill. Cook rather slowly until well browned all over, turning them frequently.

Times for Grilling Meat.—The following table gives approximate times which vary according to thickness of the meat:—

Steak: under-done	10–15 minutes
well done	15–20 minutes
Lamb or mutton chops	10–20 minutes
Pork chops	25 minutes
Veal cutlets	15–20 minutes
Liver	5–10 minutes
Kidneys	10 minutes
Bacon rashers	2–3 minutes
Ham	10–15 minutes
Sausages	10–15 minutes

FRYING

There are two main methods of frying, shallow frying and deep frying.

Shallow Frying

This is suitable for foods like chops, sausages, bacon, fish, pancakes, eggs, cooked potatoes or vegetables, which only require sufficient fat to prevent them from sticking to the frying-pan, or made-up dishes, such as fish cakes or rissoles, which need sufficient fat to half-cover the food.

Heat the fat until just smoking hot in the pan before putting the food in. Cook the food quickly on both sides until the surface is lightly browned. Reduce the heat and finish cooking gently. When cooked lift from the pan, allow fat to drain off, and then place on a crumpled piece of kitchen paper to finish draining; arrange on a hot dish, and serve at once. Any remaining fat should be strained into a bowl for further use. Fat used for frying fish should be kept separately. It is important to avoid over-heating of the pan and fat when shallow frying, or particles of food may become burnt and spoil the flavour of the dish.

Special Directions

Bacon.—Cut the rinds off the bacon, then put these and the rashers in a cold frying-pan, place over a gentle heat and cook until the bacon fat is transparent and the rashers just begin to curl. Remove from the pan, then, if convenient, use the fat for frying potato cakes, cooked sliced potatoes, or an egg. When frying an egg remember to baste it with the hot bacon fat in order to cook the top surface properly.

Sausages.—Heat about a tablespoonful of fat in the pan. Prick the sausages with a fork and put them in the hot fat and fry over very gentle heat, turning them until they are lightly browned on all sides. The secret of cooking sausages is to cook them very slowly—but they must be thoroughly done and nicely browned.

Fish.—*Fillets.*—Wipe and dip in seasoned flour. Have a small quantity of fat smoking hot in the pan and place the fillets in this. Fry until lightly browned, then turn and fry on the other side. Cook gently until the flesh is white and firm. As fish breaks easily, it must be handled carefully.

Herrings.—Very little fat is required for frying herrings, as they are a naturally oily fish; in fact, it is quite possible to fry herrings without any fat in a really strong iron frying-pan. Scale, clean, wash, and dry the herrings. Sprinkle the pan with salt and heat gently at first, shaking occasionally. Continue heating until the pan is almost red hot, then lay in the herrings. Fry on each side until golden-brown and crisp—3 to 4 minutes each side. Serve piping hot.

Chops and Steaks.—Wipe the meat and place in a little hot fat in the pan. Fry quickly on both sides until lightly browned, then reduce the heat and cook very gently until the meat is tender. (Test with a thin skewer if necessary.) Remember when once the outside surfaces are brown the heat must be reduced, otherwise the meat will be dry on the outside and unpleasantly raw inside. The time for cooking chops and steaks depends on the thickness and texture of the meat, but a thin chop or steak will take about 10–12 minutes.

Liver.—Slice the liver across the grain in pieces ¼ in. thick, toss in seasoned flour, and fry as for chops and steaks.

Deep Frying

This is suitable for made-up dishes such as croquettes, rissoles, fritters, fish coated with batter or egg and bread-crumbs, whitebait, doughnuts, etc. For this method a deep-fat frying-pan is used with a fitted wire basket, and there must be sufficient fat to allow the food to be completely submerged, *i.e.*, about three-quarters filled. Suitable fats are olive oil, lard,

block suet, or clarified dripping. All food cooked in deep fat, with the exception of potatoes and pastry, must be coated with egg and bread-crumbs or batter; flour is not a suitable coating for deep-fat frying. Heat the fat until a faint blue smoke rises from it. Any excess bubbling or spitting is due to moisture in the fat, and the pan must be heated very gently until this ceases. The prepared food should be placed in the basket, and the pan of fat drawn to the side of the heat. Lower the basket into the fat and replace over the flame or hot-plate. If the food is added while the fat is over the heat it may bubble over and catch on fire. Cook the food until it is golden-brown, lift the basket and drain off surplus fat. Turn the food on to crumpled kitchen paper to finish draining, and finally arrange in a dish and serve very hot. When large quantities of food are to be cooked, fry a little at a time to avoid lowering the temperature of the fat.

Should the fat accidentally catch on fire, turn off the current or burner immediately, and place a lid quickly over the pan of fat.

The used fat can be strained into a container for further use.

The temperature for deep-fat frying is very important. If it is not hot enough the food becomes sodden with grease, and if too hot the outside will be burnt. Average temperatures vary between 395° and 350° F., according to different foods.

If a thermometer is not available the temperature may be tested as follows: put one or two 1-in. cubes of bread into the hot fat; if they take 60 seconds to brown, the fat is about 350–365° F.; if they take 40 seconds, it is about 365–382° F.; if they take only 20 seconds, the fat is about 382–390° F.

Special Directions

Egging and Crumbing.—This is suitable for fillets of fish, cutlets, rissoles, fish cakes, and croquettes. First coat the food lightly with seasoned flour. Have some beaten egg on a plate, and taking one piece of food at a time, brush it all over with the beaten egg, using a pastry brush. Have ready some fine bread-crumbs on a piece of kitchen paper. Lift the coated food on to the crumbs, carefully draining off any excess egg. Holding the sides of the paper, toss the crumbs so that they cover the food. Pass from one hand to the other to remove any loose crumbs, then place in the frying-basket.

Coating Batter.—Batter is a suitable coating for fritters (fruit or vegetable), fillets of fish, kromeskis, etc. Any good batter recipe can be used—it should be mixed to the consistency of thick cream. Place the food to be cooked, a piece at a time, in the batter, allow any excess batter to drip off, and place immediately in the smoking fat. When golden brown and cooked through, drain carefully and dish.

Chipped Potatoes.—Special care must be taken when frying potatoes in deep fat. They must be thoroughly dried, otherwise when they are placed in the fat will splutter and an accident may be caused.

First peel the potatoes and cut them into chips, straws, or scallops. If they have to be prepared in advance leave in cold water. Just before frying drain off the water, spread them out on a clean dry cloth, rub them carefully with the cloth so that all surfaces are dry, then place in the frying-basket. When lowering the basket into the fat take great care that the fat does not froth over.

Chipped potatoes take about 20 minutes to cook. To ensure they are not sodden cook them until tender, but not crisp, then lift out the basket and reheat the fat. When at smoking point, replace the basket in the fat and cook until brown and crisp. Drain carefully, and sprinkle with salt before serving.

To Render Down Fat

Any pieces of meat fat can be used to prepare frying-fat. Cut the fat into pieces about ½ in. square, removing any scraps of meat or gristle, put into a pan, cover with water, and allow to boil slowly for several hours until the water is driven off and the pieces of fat are fried and shrivelled. Strain off the fat.

Another method is to place the cut-up fat in a tin and cook it in a slow oven to extract the fat. This method is easier but is more wasteful of fat, as much of it is left in the particles of skin when drained.

ROASTING

This is one of the most popular ways of cooking meat, poultry, and game. There are two different methods of roasting; one for good-quality and tender joints, the other for poorer-quality meats. In either case the preparation of the meat is the same.

Wipe and weigh the meat, tie in shape if necessary, and stand on a trivet in a shallow roasting-tin. Always place the meat fat side up to allow it to melt, and baste the meat as it does so. A tablespoonful or so of fat should be placed on the meat, and a piece of fat bacon on lean meats, such as game or veal. Basting is not necessary. Small joints such as breast or loin of lamb or veal can be boned and stuffed. Prepared vegetables should be placed round the joint. When the joint is cooked, it should be taken out of the oven and the gravy made in the tin. Remove the meat and vegetables from the fat, and place on a dish to keep warm. Pour off the dripping, leaving the sediment in the bottom. Add to it sufficient flour to soak up the fat—about 2 teaspoonfuls to every 1 pint of gravy needed—mix with the sediment and then place over the heat and stir until the flour is a golden brown. Pour on liquid, which should be stock or vegetable water. Bring to the boil and season. It may be necessary to add a few drops of gravy browning. Gravy should be of a thin pouring consistency, and free from grease.

If a covered roasting-tin is used the top should be removed 30 minutes before the meat is done, in order to brown the outside.

Times and Temperatures for Roasting Meat

Method 1.—Place the joint in an oven heated to 425° F. Reduce the temperature to 400° F., and allow the following times for cooking: beef, 15 minutes to the lb. and 15 minutes over; beef, thick cut or rolled, 30 minutes to the lb.; mutton, 25–30 minutes to the lb.; mutton, stuffed, 30–35 minutes to the lb.; veal and pork, 30–40 minutes to the lb.

Method 2.—Put joint into a cold oven, raise the temperature to 300–350° F. and allow: beef, 25–35 minutes to the lb.; beef, thick cut or rolled, 30–40 minutes to the lb.; mutton, 30–40 minutes to the lb.; mutton, stuffed, 35–45 minutes to the lb.; veal and pork, 40–50 minutes to the lb.

Bird	*Time*
Chicken	1 hour
Duck	1–1½ hours
Goose	1½ hours or longer
Guinea Fowl	30–45 minutes
Pigeon	20–30 minutes
Turkey	15 minutes per lb. (weight after dressing) for birds up to 14 lb.; 10 minutes per lb. for larger birds
Pheasant	30–60 minutes according to size
Grouse	½–¾ hour
Partridge	25 minutes

POT ROASTING

This is a particularly suitable method for tough joints, and is also an alternative to roasting when no oven is available.

Rub the meat over with seasoned flour. Melt some dripping, allowing about 1 tablespoonful to each lb. of meat, in a saucepan with a well fitting lid. Brown the meat on all sides, and add about a ¼ pint of water. Slip a trivet under the meat, cover tightly, and leave to cook gently until tender, turning the joint from time to time. The average joint takes 1½–2 hours. Vegetables such as diced carrot, turnip, or onion can be added to the pot an hour before serving. Herbs can be used for flavouring.

STEAMING

One of the most economical methods of cooking food, and one which has the advantage of retaining mineral salts which otherwise may be dissolved out when food is boiled in water. The chief points to remember are that the steamer must never be allowed to boil dry and the water must not be allowed to go off the boil.

Methods of Steaming

1. *In a Steamer with Perforated Base Placed over an Ordinary Saucepan.* The steamer must fit the saucepan well. Soups or a vegetable can be cooked in the bottom of the steamer, a pudding with some vegetables round it can go in the top, and if required fish can be steamed on a plate on top of the steamer.

2. *In a Tiered Steamer.* This is an extremely useful utensil, but care must be taken to see that the steam enters all compartments, and the regulator knobs should be checked each time it is used. Different dishes can be cooked in each tier without any fear of flavours becoming mixed.

3. *In Jam-jars, Basins, or Moulds in a Pan of Boiling Water.* The water should reach half-way up the jar or basin. For a delicate dish, such as a soufflé, the mould or tin should be placed on an upturned saucer, pastry cutter, or tin. The water in the pan may be replaced by soup, or vegetables can be cooked in the water and different foods in each jam-jar.

4. *In a Compartment Steamer–Saucepan.* These pans are sold with several compartments fitted into the saucepan, and are useful for small families. The method is the same as when using pudding-basins.

5. *In a Double Saucepan.* This is a suitable way of cooking sauces, stews, porridge, etc. They take longer, but there is no fear of their boiling or burning, and sauces do not need constant stirring.

Meat.—Any joint of meat can be steamed. Allow twice as long as for boiling. Soak salted meat for 3 hours beforehand.

Poultry.—The time depends very much on the size and age of the bird. A good way of cooking an old fowl is to steam it until it is tender, then to brown it in a hot oven (450° F.) for ½–¾ hour.

Fish.—Prepare the fish as for boiling. Place large cuts or whole fish directly in the steamer. Small fillets or thin cutlets will cook satisfactorily if laid on a greased plate with a tablespoonful of milk and seasoning. Cover with a lid, then lay the plate on top of the steamer or pan.

Time for Steaming

Fish.—For a large fish allow 15 minutes to each lb. and 15 minutes over. Cook fillets until the flesh is firm—about 20 minutes.

Vegetables.—Steaming is only suitable for root vegetables, as in green vegetables the loss of vitamins and mineral salts is too high, and flavour and colour are likely to be impaired. Potatoes can be scrubbed and steamed in their jackets. Other root vegetables should be peeled. Sprinkle the prepared vegetables liberally with salt. Allow half as much time again as for boiling.

Puddings.—To keep out the moisture caused by condensation, the pudding should be covered with greased paper or a cloth dipped in hot water and floured. A basin-cover or string should be tied round the basin, so that it may be easily lifted out of the steamer.

Suet puddings need 3 hours or longer. Sponge puddings in small dariole moulds cook in 20 minutes; larger puddings take ¾–2 hours, according to the size. Allow plenty of room in the basin for the pudding to rise.

Custards.—The water should be only just boiling for these, as they curdle if the temperature becomes too high. Remove as soon as they are set (about ½ hour.)

STEWING

A long, slow method of cooking in a liquid kept just below simmering point. A good strong pan with tightly fitting lid should be used, or alternatively a casserole, steamer, or double boiler. Stewing can be done either in the oven or over a low heat. It is important not to raise the temperature above boiling point, or the food becomes tough or broken up.

Stewed Fruit

Preparation.—Peel, core, or stone and, if necessary, cut up into neat pieces.

Cooking.—To keep individual pieces of fruit whole and of good shape (*e.g.*, to serve as stewed fruit, for fruit in jelly, fruit trifle, and so on) stew them gently in a syrup made from sugar and water. The proportions will vary with the juiciness and sweetness of the fruit, but ¼–½ pint water and 2–4 oz. sugar to 1 lb. fruit is the average. Lift out the fruit, simmer the juice until it is slightly syrupy, and pour over the fruit.

If the fruit is required stewed to a mash to make into a purée (for fruit fools, creams, and so on), it is better to cook it without sugar and in the minimum of water until tender, and then to sweeten it, since the addition of sugar to the raw fruit toughens the skin and may prevent it mashing properly.

Some fruits are improved by the addition of other flavouring. Apples may be flavoured with lemon juice, grated lemon rind, cloves, cinnamon stick, or marmalade (remove cloves or cinnamon before serving), pears with cloves or cinnamon stick. Plums may be flavoured with their kernels or a few sweet almonds, rhubarb with root ginger, cinnamon stick or strip of lemon rind; remove before serving.

Stewed Dried Fruit

Wash ½ lb. fruit, such as prunes, very thoroughly, add ½ pint water, and allow to soak for at least 12 hours. Put the fruit in a saucepan with the water and 1–4 tablespoonfuls sugar, according to fruit, and bring to the boil, simmer gently until tender. Remove the fruit, boil the juice for a few minutes, until syrupy, then pour it over the fruit. Alternatively, the fruit may be steamed until tender—it will take at least half as long again as stewed fruit.

Meat Stews

Brown.—For this type the meat, vegetables, and flour are fried before stewing. Stewing steak is commonly used for brown stews, but other meats such as oxtail, kidney, and liver may be used.

White.—Mutton, veal, or rabbit is generally used for white stews, and the meat and vegetables are not fried first. Irish stew is an example of a thin white stew, while a fricassee is a thickened white stew.

The cheaper and coarser the meat, the longer it takes to cook. Most types of stew require at least 2 hours, and some varieties, such as oxtail and brisket, may take 3 or even 4 hours. Herbs, spices, and vegetables should be added in moderation to give flavour and interest to the stew.

For recipes see following chapter.

PRESSURE COOKERY

By cooking foods in specially designed pressure cookers it is possible to cook at temperatures above the normal boiling point of 212° F. This is a particularly valuable method of cooking foods which normally require long, slow cooking, such as stews, soups, root vegetables, tough joints of meat, etc. Considerable time and fuel can be saved.

There are many varieties of pressure cooker now on the market, in each case the manufacturers' instructions should be carefully followed, and the directions for sealing the cooker and controlling the pressure thoroughly understood.

With most cookers the prepared food is placed in the pan with the required quantity of liquid. The lid is fixed into position and the pan is placed over a high heat, and the contents brought to pressure point. The heat is then reduced, and the cooking time is calculated from that point.

The following points should be remembered:

1. The cooker should never be filled too full—not more than two-thirds full for solid foods and half-full for liquids, cereals, and preserves.

2. The times given in the charts should be followed, but there will probably be slight variations due to the thickness and quality of the food, especially meat and poultry, etc.

3. Always allow pressure to drop to normal before attempting to open the pan; either reduce pressure immediately by running cold water over the side, or in the case of milk puddings, cereals, dried vegetables, and stewed fruit, allow the cooker to cool slowly for 5–10 minutes at room temperature.

4. After use the cooker should be carefully washed. Store with the lid off so that the air can circulate.

Times for pressure cooking cannot be guessed. The following tables will serve as a guide, though fuller instructions should be followed from the manufacturers' or other special recipe book.

Pressure-cooking Time-table for Meat or Bird

Meat or bird.	Water.	Cooking time (at 15 lb. pressure).
Beef—Boil	1 pt.	9–10 minutes per lb. plus 10 minutes
Roast—pre-fry	¼–½ pt.	" " " "
Mutton, Lamb, and Veal—Boil	1 pt.	10–12 minutes per lb. plus 10–12 minutes
Roast—pre-fry	¼–½ pt.	" " " "
Pork—Boil	1 pt.	12 minutes per lb. plus 12 minutes
Roast—pre-fry	¼–½ pt.	" " " "
Chops (Veal, Pork, Mutton, and Lamb)—pre-fry	¼–½ pt.	5–6 minutes according to thickness
Young Chicken, Duck, Guinea Fowl, Pheasant, and Grouse	"	6–8 minutes
Partridge and small birds such as Snipe and Woodcock	"	15 minutes in all
Old Fowl (approx. 3 lb.)	1 pt.	30–35 minutes, according to age

Pressure-cooking Time-table for Steamed Fish

Fish.	Water.	Cooking time (after 15 lb. pressure is reached).
Bream, Halibut, Fresh Haddock, Hake, Skate, Turbot	¼–½ pt. water or to level of rack, but extra water when fish is in greaseproof paper	3–4 minutes for cutlets; 4–5 minutes per lb. for whole fish
Cod	" " "	3–4 minutes for cod steaks; 4 minutes per lb. for whole fish
Haddock (dried)	½ pt. milk and water	3–5 minutes, according to size
Herrings, Trout, Mackerel	¼ pt. water	Melt a small knob of fat at bottom of cooker, dip fish in seasoned flour and cook rapidly on both sides in hot fat. Lift on to rack and add ¼ pt. water, and continue cooking as above, allowing 4–6 minutes according to size
Plaice or Sole	¼–½ pt. water or to level of rack, but extra water when fish is in greaseproof paper	Whole fish, 2–4 minutes per lb. according to size. Fillets, 2–3 minutes
Salmon Steaks	" " "	6–7 minutes, according to thickness. Be sure to wrap fish in well-greased paper
Scallops	" " "	4–5 minutes

Pressure-cooking Time-table for Vegetables

Vegetables.	Water.	Cooking time (at 15 lb. pressure).
Artichokes (Jerusalem)	¼–½ pt. or to level of rack	8–10 minutes
(Globe)	" "	10 minutes
Asparagus	" "	2–3 minutes
Beans (Broad)	" "	3–4 minutes
(French)	" "	3 minutes
(Runner)	" "	2–3 minutes
Beetroot	" "	10–35 minutes, according to size and age
Brussels Sprouts	" "	3–4 minutes
Cabbage, Spring Greens	" "	2 minutes
Carrots (diced)	" "	2–3 minutes
(whole, young)	" "	3–5 minutes
(large)	" "	8 minutes
Cauliflower (sprigs)	" "	2 minutes
(whole)	" "	5–6 minutes
Celery	" "	2–3 minutes
Corn on the Cob	" "	4 minutes
Leeks	" "	3–5 minutes
Onions (whole)	" "	10 minutes
(sliced)	" "	3–4 minutes
Parsnips	" "	As for carrots
Peas	" "	1–2 minutes
Potatoes (new)	" "	10 minutes
(old)	" "	8–10 minutes
Spinach	" "	1–2 minutes
Swedes	" "	5 minutes
Turnips	" "	5 minutes
Vegetable Marrow	" "	3–4 minutes

Pressure-cooking Time-table for Dried Vegetables

Vegetable (4 oz.).	Water.	Cooking time (after 15 lb. pressure is reached).
Butter and Haricot Beans (soak 2 hours)	½ pt.	15–20 minutes
Lentils	"	20–25 minutes
Peas (soak 2 hours)	"	15–20 minutes
Split Peas	"	10–15 minutes

Pressure-cooking Time-table for Cereals

Cereal (4 oz.).	Water.	Cooking time (at 15 lb. pressure).
Macaroni	1 pt.	5–8 minutes
Noodles	"	4–6 minutes
Spaghetti	"	6–8 minutes
Rice	"	5–7 minutes
Pearl Barley	"	20–25 minutes

Pressure-cooking Time-table for Fresh Fruit

Fruit (1 lb.).	Water.	Cooking time (at 15 lb. pressure).
Apples (sliced)	½ pt.	1–2 minutes
Blackberries	"	2 minutes
Black-currants	"	2 minutes
Cherries	"	2 minutes
Gooseberries	¼ pt.	2 minutes
Pears (hard cooking)	"	6–7 minutes
Plums	¼ pt.	3 minutes
Raspberries	"	Merely bring to pressure
Rhubarb	"	2 minutes

Pressure-cooking Time-table for Dried Fruit

Previously soaked for 12 hours

Fruit (1 lb.).	Water.	Cooking time (at 15 lb. pressure).
Apple rings	½ pt.	5–6 minutes
Figs	1 pt.	10–15 minutes
Prunes	½ pt.	6–10 minutes
Apricots and Peaches	½ pt.	6–10 minutes

III. DIRECTIONS AND RECIPES FOR TYPICAL DISHES

SOUPS

The basis of all good soup is stock, and it should be used when available. Stock can be made from any scraps of meat, bones—cooked or uncooked—and root vegetables. Fish stock must be made separately and used only for fish soup.

Bone Stock.—Use a large pan with well-fitting lid and place the bones in it with pieces of root vegetable, and a *bouquet garni* (bunch of herbs). Cover with cold water, season, and simmer for 2–3 hours. If there is any fat with the bones strain off the liquid, allow to cool, and skim off the fat. Stock should be boiled up every day with additional bones and vegetables. The pot must be emptied and cleaned about every third day.

Vegetable Stock.—Cut up a variety of vegetables, being careful to avoid including too much of a strong-flavoured variety such as turnip. Cover with cold water and flavour with seasoning, a bay leaf, clove, a blade of mace, and herbs. Simmer until a good flavour is obtained. Use fresh.

Fish Stock.—Put fish bones and skin with herbs, spice, and seasoning into a pan. Cover with water and simmer for 1 hour. Use same day.

Soups can be divided into the following groups: purées, thickened soups, clear soups, or consommés, broths, and fish soups.

Purées are made from puréed vegetables and seldom require additional thickening.

Thickened Soups are made from vegetables and other ingredients simmered in stock. They are usually sieved and then thickened according to their ingredients.

Clear Soups or **Consommés** consist of good stock carefully cleared, and entirely free from fat, and served with a garnish which has been cooked separately. Sherry can be added if desired.

Broths are made of stock, diced meat, and vegetables. They are thickened with barley or rice, and are never sieved.

Fish Soups are made from a foundation of fish stock.

Consommé

½ lb. lean beef	12 peppercorns
1 small carrot	2 cloves
1 small onion	A blade of mace
A piece of turnip	The whites and shells of 2 eggs
A small stalk of celery	Salt, if necessary
2 quarts best-quality (or first) stock	A little sherry
A bouquet garni	

Shred the meat very finely, put it into a bowl with enough cold water just to cover, and allow it to soak for about ½ hour. Prepare the vegetables and cut each into four. Put the stock, from which all trace of fat has been removed, into a deep, lined saucepan, add the meat and the water in which it has soaked, the vegetables, herbs, and spices. Lastly, add the whites and crushed shells of the eggs. Put over gentle heat, whisk continuously and bring almost to boiling point; a thick froth should form on the top of the liquid. Stop whisking and continue heating until the froth rises in the pan, then reduce the heat and allow the soup to simmer for a few minutes. Tie a clean white cloth to a jelly stand or to the four legs of an upturned chair and scald with boiling water, then gently pour in the soup. When the consommé has dripped through, strain it a second time—passing it through the frothy egg-whites, etc., to make it clear and sparkling. If necessary, the consommé may be strained a third time.

Reheat the consommé, add salt if necessary, and a little sherry to improve the flavour, but add nothing that would make it cloudy.

Tomato Soup

1 lb. tomatoes	2 oz. margarine
1 pint vegetable water	Seasoning
2 onions stuck with cloves	2 teaspoonfuls sugar
4 oz. breadcrumbs	1 pint hot milk or milk and water

Cut up the tomatoes and put them into a saucepan with all the other ingredients, except the milk. Bring to the boil and simmer with a lid on for 20 minutes, then strain and rub through a sieve. Return to the pan and reheat, then add the milk. Serve with croûtons of toast.

Potato Soup

6 potatoes	½ pint milk
2 small onions	A small bunch of watercress
1½ pints water or stock	Seasoning
1 tablespoonful flour	

Cook the potatoes and onions in the water until tender. Strain, then press through a sieve. Return to the saucepan, add the flour, blended with the liquid, and bring to the boil, stirring continuously. Wash and chop the cress, and add this to the soup, together with the seasoning. Boil for 3 minutes and serve.

Lentil Soup

¼ pint lentils	A pinch of herbs
1½ pints water	½ oz. flour
1 onion	¼ pint milk
1 carrot	Salt and pepper
½ oz. dripping	Chopped parsley
A clove of garlic	

Wash the lentils, and if possible soak overnight in the water. Fry the onion and carrot in the dripping, add the lentils and water in which they were soaked, the crushed garlic, and the herbs. Bring to the boil, simmer gently until soft, and pass through a sieve. Blend the flour and milk, add to the purée and season, bring to the boil, and boil for a few minutes to cook the flour. Sprinkle in the chopped parsley and serve.

Artichoke Soup

1½ lb. Jerusalem artichokes	2 pints stock or water
1 stalk of celery	Salt and pepper
2–3 bacon rinds	1 oz. flour
A little fat if required	½ pint milk
	Chopped parsley

Peel and slice the artichokes, chop the celery and sauté them in the fat from the bacon rinds, adding a little more fat if necessary. Add the liquid and seasoning, bring to the boil, and simmer until the vegetables are tender. Pass through a sieve and return to the saucepan. Add the flour, blended to a smooth cream with the milk, bring to the boil, and cook for 2–3 minutes, re-seasoning if necessary. Add the parsley.

Green Pea Soup

2 lb. peas	1 oz. flour or ½ oz. cornflour
1 quart stock or water	½ pint milk
A sprig of mint	
Seasoning	

Shell the peas and wash the pods in several waters. Place the pods in a pan, cover with the stock or water, and allow to simmer gently for about ½ hour, to extract flavour and colour. Strain off the stock, return to the pan with the peas, mint, and seasoning, and simmer until the peas are tender. Pass through a sieve. Blend the flour or cornflour with the milk, add to the soup, re-boil, stirring all the time, and serve.

Celery Cream Soup

Outside stalks of 1 large head of celery	Salt and pepper
1 medium-sized onion	A bouquet garni
½–1 oz. fat	1 oz. flour
2 pints stock or water	½ pint milk
	Chopped parsley

Prepare and slice the celery and onion, and sauté in the fat for about 10 minutes. Add the stock or water, seasoning, and bouquet garni, bring to the boil and simmer until the vegetables are quite tender. Pass the soup through a sieve and return to the saucepan. Stir in the flour, blended to a smooth cream with the milk and allow to boil for a further 2–3 minutes. Re-season if necessary, and add the freshly chopped parsley just before serving.

Pot au Feu

2 lb. lean beef	2 small leeks
2½ quarts water	2 stalks celery
Salt	A bouquet garni (including a small blade of mace, 12 peppercorns, and 2 cloves)
1 carrot	1 oz. seed pearl tapioca or semolina
1 turnip	
1 onion	
1 parsnip	
1 small cabbage	

Tie the meat into a neat shape, put into a large saucepan, add the water and 1 teaspoonful salt

and simmer for 2 hours. Prepare the vegetables, cut each into quarters, with the exception of the cabbage, and add to the broth with the bouquet garni. Continue to cook for another 2 hours. Cut the cabbage in two, but tie together so that it does not break whilst boiling, put into the pot and boil until tender. Serve the meat on a dish with some of the liquor; garnish with the vegetables. If liked, the cabbage may be dished separately.

To make soup from the liquor sprinkle in the seed pearl tapioca or semolina, cook for 15 minutes and serve.

The meat and broth may be served separately or together, whichever is preferred.

Simple Minestrone

1 lb. carrots	A bouquet garni
A small piece of turnip	2 tablespoonfuls macaroni
2 stalks of celery	A little ketchup
½ lb. artichokes	2 tablespoonfuls chopped parsley
1–2 onions or leeks	Grated cheese to serve separately
1 oz. fat	
2 pints stock	
Seasoning	

Prepare the vegetables and cut into small, neat pieces. Melt the fat, and sauté the vegetables in it for 5–10 minutes. Add the stock, seasoning, and bouquet garni. Cover and simmer for about ½ hour, then add the macaroni and continue cooking for a further ½ hour, or until the vegetables are quite tender. Re-season and add a little ketchup to taste. Just before serving remove the bouquet garni and add the finely chopped parsley. Serve with grated cheese handed separately.

Scotch Broth

1–1½ lb. lean beef, either runner or topside	1 turnip
2 quarts water	1 medium-sized onion
Salt and pepper	2 leeks
1 carrot	1½ oz. pearl barley
	1 dessertspoonful finely chopped parsley

Put the meat into a pan, add the water and salt, bring to boiling point slowly, then simmer gently for 1½ hours. Add the vegetables, previously cut into dice, and the barley. If you do not want the broth to be cloudy it is advisable to blanch the barley before adding it to the stock; to do this, put the grain into cold water and bring it to boiling point, strain, and add to the soup. After adding the barley and vegetables continue to simmer until both are cooked—this will take approximately 1 hour. Serve the meat separately on a dish with a little of the broth. Put the chopped parsley into the soup tureen and pour in the broth. (If the parsley is cooked it loses its green colour.) Should any fat appear on the surface of the broth it must be removed with a spoon or by gently passing a piece of clean unglazed kitchen paper over the top.

Chicken Broth

1 chicken	1 dessertspoonful seed pearl tapioca
Cold water to cover (approx. 2 quarts)	1 heaped teaspoonful chopped parsley
Salt	
1 onion	

If using a whole chicken, cut in half, after usual preparation, wash thoroughly, and remove any fat or grease, but retain the skin. Put into a pan and add the water and salt to taste. Peel the onion, cut in half, and add to the contents of the saucepan. Simmer slowly for 3½–4 hours, and if the water boils away, add more. Strain, stand aside until cold, and remove any grease that may have settled on the top of the stock. If time will not permit waiting for the stock to get cold, the grease may be removed by passing a sheet of kitchen paper over the top of the broth. Return the stock to the saucepan, bring to the boil, add the seed pearl tapioca, previously blended with a little of the cold broth, and cook for 10 minutes. Put the chopped parsley in the bottom of a soup tureen and pour the broth over it.

This is an excellent method of utilising an old chicken; if a young one is used, the breast and wings can be removed beforehand and used for grilling or frying.

Oxtail Soup

1 oxtail	1 bay leaf
2 onions	2 cloves
1 carrot	6 peppercorns
2 stalks of celery	Salt and pepper
1 oz. butter or dripping	1 oz. flour
3–4 pints stock	A little port wine if liked
1 oz. lean ham or bacon	Squeeze of lemon juice or a little ketchup
A bouquet garni	

Wash the oxtail, then joint it, and dry the joints. Prepare and cut up the vegetables. Melt the fat in a saucepan, and sauté the jointed oxtail and the prepared vegetables in it for a few minutes. Well cover with stock and bring to the boil. Add the ham or bacon, the herbs, and seasoning, then cover and simmer gently for about 4 hours, or until the tail meat is tender, skimming occasionally. Strain the soup, remove the meat from the tail joints, cut it up neatly and replace it in the strained liquor. Return to the saucepan, stir in the flour, blended to a smooth cream with a little water or port wine. Bring to the boil, stirring, and cook for about 5 minutes. Add more seasoning, if necessary, and a squeeze of lemon juice or ketchup to taste.

Court Bouillon

To each quart of water (or water and white wine mixed) allow:—

1 onion	A small clove
1 clove of garlic	1 tablespoonful vinegar
1 carrot	1 teaspoonful salt
Small stalk celery	Freshly ground black pepper
A bunch of herbs	

Put ingredients into a pan, cover, simmer for ½ hour or longer, strain, and use for cooking fish.

Fish Cream Soup

1 cod's head	A bouquet garni
1½ pints water	Salt and pepper
A small carrot	½ pint white sauce
¼ of a turnip	1 tablespoonful chopped parsley
½ an onion	
1 stalk of celery	

Thoroughly wash the cod's head, place in a saucepan, and add the water; bring slowly to the boil and skim well. Prepare and chop the vegetables and add with the bouquet garni to the cod's head and water. Add salt and simmer for about 1 hour. Strain, remove any flesh from the head, and cut into neat pieces. Make the white sauce or re-heat it and blend with the fish stock. Season well and add the fish and chopped parsley just before serving.

Soup Garnishes

Bacon.—Cut into small strips or dice and fry lightly.

Cheese.—Grate the cheese (preferably Parmesan or dry Gruyère), and if desired mix it with either chopped parsley or watercress; hand it separately or sprinkle it on the soup just before serving.

Cheese or Herb Dumplings.—Mix together breadcrumbs and grated cheese in equal proportions. Season with salt, pepper, mustard, and mixed herbs, and bind with beaten egg, adding a few drops of piquant sauce if desired. Form into small balls and poach in the soup 15–20 minutes before serving.

Fried or Roasted Croutons.—Cut bread into slices ¼ in. thick, and then into triangles or fancy shapes; bake until golden-brown and crisp, or fry in smoking hot fat, drain, and serve hot. Alternatively, the slices of bread may be toasted first and then cut up.

Leek.—Chop and fry.

Macaroni, Spaghetti, Noodles, Shells, etc.—Break into short lengths if necessary, and add to the soup about ½ hour before serving.

Mushrooms.—Cut into thin slices and fry.

Onions.—Slice into rings or chop finely and fry.

Rice.—Add dry-boiled rice and freshly chopped parsley or chives just before serving the soup. Rice may also take the place of barley in mutton broth.

Vegetables.—Cut raw carrot, turnip, etc., into "matchsticks" or small balls, shred cabbage and slice celery, and cook them separately for 10 minutes in some stock; alternatively, tie them in muslin, to keep them together, and cook them in the soup. Sprinkle the pieces into the individual soup plates or cups before serving.

Watercress.—Float leaves on cream soups.

FISH

For success in cooking fish good-quality fish in a fresh condition is essential. This should have firm flesh, bright eyes, red gills, clear markings, and be free from unpleasant smell. Sea-water fish is divided broadly into two categories, white fish, such as cod, sole, plaice, haddock, whiting, etc., and oily fish, such as herring or mackerel. Fresh-water fish and shell-fish are more expensive, and usually require special attention for cooking and serving.

Most fish can be steamed, poached, baked, grilled, or fried as directed on S3–7. Fish should always be carefully prepared by washing under cold water, removing the head or scales, and trimming the fins and tail. Sole and plaice may be skinned or filleted.

Fish Pie

1 lb. cooked fish	Salt and pepper
1½ oz. margarine	1 tablespoonful parsley
1 oz. flour	Squeeze of lemon
½ pint milk	Creamed mashed potato

Skin and bone fish and flake finely. Melt 1 oz. fat, stir in flour and cook for a few minutes without browning. Stir in milk and bring to the boil. Add seasoning, parsley, lemon juice, and the fish, put in a fireproof dish and cover with mashed potato. Dot with margarine and heat in a moderately hot oven (400° F.) for about 20 minutes.

Fish Cakes

Flour	About 1 lb. boiled potatoes
⅛ pint milk	½ lb. cooked fish
⅛ pint fish stock	2 teaspoonfuls chopped parsley
Salt and pepper	Fat for frying
A knob of margarine or butter	Egg and bread-crumbs if required
¼ teaspoonful mustard	
A few drops of vinegar	

Blend 1 tablespoonful of flour to a smooth cream with the milk, add the fish stock and bring to the boil, stirring. Cook for 2–3 minutes, then season with salt and pepper and beat in the knob of fat and the mustard, blended with a few drops of vinegar. Mix well and cool slightly.

Mash the potatoes, rubbing them through a sieve if necessary, and mix them with the flaked fish and chopped parsley. Bind with the sauce, adding more seasoning if required, then spread the mixture on a plate and allow to cool. Divide into 6–8 portions and shape into flat cakes or croquettes. Dust with flour and fry in a little hot fat until well browned and crisp on both sides, or coat with egg and crumbs and fry in deep fat. Serve with a good sauce, such as parsley, mustard, or anchovy sauce.

Fried Fish with Tomatoes

8 fillets of flat fish	Button mushrooms
1 egg	Tomato lilies
Brown breadcrumbs	Lemon butterflies
Fat for frying	Parsley

Coat the filleted fish with egg and breadcrumbs. Heat the fat, fry the fish to a golden colour, drain thoroughly, and keep hot. Fry the mushrooms, grill the tomato lilies, put them round the fish and garnish with lemon and parsley. Alternatively, halve the tomatoes and fry them to serve with the fish.

Baked Curled Whiting

4 medium whiting	Browned breadcrumbs
Fat	Carrot balls
Seasoning	Parsley and lemon

Prepare the fish and remove the eyes. Curl each whiting round, the tail in the mouth or through the eye-sockets. Brush with melted fat, sprinkle with seasoning and fine breadcrumbs. Dot with fat and bake in a greased tin in a moderate oven (350° F.) for about ½ hour. Garnish with carrot balls, parsley, and lemon, and serve with tomato sauce.

Baked Stuffed Sole

1 large sole	Lemon butterflies
Fish forcemeat	Cucumber cones
A little fat	Duchesse potatoes

Trim the fish, make an incision down centre back and loosen flesh close to the bone on each side. Stuff with good fish forcemeat and put on a greased baking-tin. Cover with greased paper and bake 20–30 minutes in a moderately hot oven (400° F.). Lift on to a hot dish and garnish with the lemon butterflies, cucumber cones, and duchesse potatoes.

Baked Stuffed Haddock

1 fresh haddock	Flour
Savoury stuffing	Shavings of margarine

The head of the fish may be removed or not, according to individual taste. If it is left on, the eyes should be taken out. Wash and trim the fish, then dry and stuff it, sewing or skewering the opening to keep the stuffing in place. Curl the fish to form an "S" and put into a greased tin. Dredge lightly with flour, dot with margarine, and bake in a moderately hot oven (400° F.), basting occasionally for about 30 minutes.

Creamed Fish au Gratin

¾ lb. white fish	2 tomatoes
¾ pint milk and water	1 oz. margarine
1 small onion	1 oz. flour
A bunch of herbs	2–3 oz. cheese
Salt and pepper	Chopped parsley
1 lb. boiled potatoes	

Place the fish in a saucepan with the liquid, sliced onion, herbs (tied in muslin), and seasoning, and simmer gently for 10–15 minutes, or until the fish is cooked. Lift out the fish, remove any bones and thick skin, and place in flakes in a fireproof dish lined with a layer of sliced, boiled potatoes. Skin and slice the tomatoes and arrange in a layer on the fish, sprinkling with salt and pepper.

Melt the margarine and add the flour to make what is called a "roux." Add the liquor in which the fish was cooked (making up to ½ pint if necessary) and bring to the boil, stirring continuously. Boil for 2–3 minutes, then add half the cheese, season with salt and pepper, and pour over the fish. Sprinkle with the remainder of the cheese and place in a moderate oven (350° F.) to heat through and brown the top. Before serving garnish with chopped parsley.

Grilled Salmon Steaks

Salmon steaks about 1 in. thick	Lemon
Oil or melted fat	Maître d'hôtel or anchovy butter
Seasoning	

Wipe the steaks, brush with oil or melted fat, and sprinkle with seasoning. Cook under a hot grill for 10–15 minutes, until the flesh comes away from the bone when tested with a skewer. Serve garnished with lemon and a pat of maître d'hôtel or anchovy butter on top of each steak.

Grilled Trout

Clean and dry the fish, split them open and remove the backbone. Brush the trout over with melted fat or olive oil, and season with salt, pepper, and lemon juice. Lay them on a hot grill and cook for 5–10 minutes on each side. Serve at once with cut lemon and watercress, or peas.

Oysters au Naturel

Fresh oysters	Bread and butter
Salt	Lemon and parsley or cress to garnish
Cayenne pepper	
Lemon juice or vinegar	

Serve the oysters very cold, opened, and on the deep shell. Sprinkle with salt, a touch of Cayenne, and a squeeze of lemon juice or a little best-quality vinegar. Serve with thin slices of bread and butter or with rolls, and garnish with lemon and parsley or cress.

Fried Oysters (Pigs in Blankets)

Cut thin rashers of bacon in half. Wrap each oyster, previously dried, in a slice of bacon, and fasten together with a tiny wooden skewer. Lay on a towel till the last minute to get entirely dry, and brown very quickly in a hot frying-pan. Place two "pigs" on a square of hot toast, and serve with a little of the liquid from the pan poured over; garnish with parsley and serve at once.

Dressed Lobster

Twist off the claws and the legs and crack each one carefully, using either a hammer or heavy

weight. Hold the lobster firmly and bend it in order to separate the body from the tail section. Using scissors, then a sharp knife, cut the tail in half lengthways from underside. Remove dark cord. Remove bony part from the body; discard the "dead men's fingers" and stomach, found in head. Leave the tail meat in the shell. Mix the rest with a little mayonnaise, salt, pepper, and a squeeze of lemon juice. Pile on to a bed of lettuce, and serve with watercress, sliced tomato, and cucumber. Garnish with some of the small claws and coral, if present. If preferred, the large claws may be served already cracked so that the flesh can be easily removed.

Lobster au Gratin

1 lobster	¼ pint milk and stock mixed
2–3 mushrooms	Salt and pepper
1 onion	1 teaspoonful browned breadcrumbs
½ oz. fat	Watercress
½ oz. flour	

Cut the lobster in half lengthwise, remove the meat and divide into neat pieces. Peel and slice the mushrooms, and peel, slice, and chop the onion roughly; fry both lightly in the fat. Add the flour, mix thoroughly and pour in the liquid, stirring until the sauce boils and thickens. Season, simmer for several minutes until the onion and mushrooms are tender, then add the lobster meat and a little of the grated cheese. The mixture should be of a thick, creamy consistency. Re-heat the meat in the sauce, pile into the two halves of the lobster shell, sprinkle with the remaining cheese and the breadcrumbs, and brown quickly under the grill or in a hot oven (450° F.) on the top shelf. Serve immediately, garnished with watercress.

Creamed Shrimps

½ pint shrimps	Seasoning
½ pint white sauce (hot)	Breadcrumbs
1 oz. cheese	

Put the picked shrimps in the white sauce, grate the cheese and add half of it, with seasoning, to the mixture. Place in small fireproof ramekin dishes, sprinkle with the rest of the cheese and a few bread-crumbs, and heat through in a hot oven (425° F.) for about 10 minutes. Serve very hot, garnished with hot shrimps.

Prawn Cutlets

4 oz. shelled prawns	A few drops vinegar
1 oz. margarine	A pinch of nutmeg
1 oz. flour	Egg and breadcrumbs
½ pint milk	Fat for frying
Salt and pepper	Whole prawns to garnish

Chop the prawns. Melt the fat, add the flour, and make a roux. Gradually add the milk and cook the sauce thoroughly. Add all the seasoning, then spread the mixture on a plate and allow to cool. Shape into eight cutlets, and egg and crumb them. Fry in smoking hot fat until golden-brown. Garnish with whole prawns, and serve either hot or cold.

Crab Salad

1 cooked crab	1 lettuce
Salt and pepper	Tomatoes
Salad cream	Watercress

Remove the meat from the crab shell, keeping the dark and white meats separate. Season with salt and pepper and add a little salad cream. Arrange the lettuce on a glass dish, put the dark meat in the centre and the white meat around. Garnish with sliced tomatoes, the watercress and the crab legs.

Mussels à la Marinière

2–3 dozen mussels (cooked)	½ pint mussel liquor
1 oz. butter	½ pint milk or wine
1 small onion	1 teaspoonful chopped parsley
1 tablespoonful flour	Pepper and salt

Heat the mussels. Melt the butter in a saucepan, add the onion (very finely chopped), and cook slowly for a few minutes. Stir in the flour and allow it to cook, then add the mussel liquor and milk or wine, and stir until boiling. Allow this sauce to simmer slowly for at least 5 minutes, add the parsley and seasoning and pour over the mussels.

Stewed Scallops with Cheese

6 scallops	1 oz. grated cheese
Salt and pepper	Toast snippets and lemon to garnish
Lemon juice	
½ pint white sauce	

Wash and drain the scallops, discard the beard and the black part, and cut the remainder into quarters. Put into a greased pan, sprinkle with salt, pepper, and lemon juice and pour over the white sauce. Simmer very gently for about 10–15 minutes, until tender, and stir in the cheese. Serve garnished with toast snippets and lemon.

Herrings in Oatmeal

2 herrings	½ teaspoonful salt
1 oz. medium oatmeal	¼ teaspoonful pepper
1 teaspoonful dry mustard	1 oz. dripping

Clean the herrings and split them open, removing the backbone. Mix the oatmeal and seasonings together. Brush the herrings with melted dripping and coat with seasoned oatmeal. Fry or cook under the grill for 5–6 minutes.

Soused Herrings

Wash and trim the herrings. Season and roll up from head to tail. Place in a pie-dish and cover with vinegar and water (equal quantities), spiced with 2 cloves, 1 bay leaf, and seasonings. Bake in a slow oven (300° F.) for ¾ hour. Serve hot or cold.

MEAT

Roasting is the most popular method of cooking meat, but it should be reserved for good-quality and good-sized joints. Poorer-quality joints braise or pot roast well, while the cheaper cuts of meat are better stewed. Small cuts of meat like chops, fillet steak, cutlet, liver, etc., are usually grilled or fried.

Directions for roasting are given on S6, but the following accompaniments can be served with roast meat:

Beef.—Yorkshire pudding and horseradish sauce.
Mutton.—Red-currant jelly or onion sauce.
Lamb.—Mint jelly or mint sauce.
Veal.—Forcemeat balls and bacon rolls.
Pork.—Sage-and-onion stuffing and apple sauce.

Mixed Grill

This consists of a selection of foods suitable for grilling, such as a chop, kidney and sausages, or a steak, liver and sausages, served with grilled halved tomatoes, mushrooms, chipped potatoes, and maitre d'hôtel butter (S21). Prepare the various items for grilling, and season all meats on both sides with salt and pepper and a little lemon juice, if liked. Brush all the pieces over with melted fat, and start by grilling the foods which require the longest time, so that they are all ready at the same time.

Grilled Lamb Chops and Peas

Lamb chops	New carrots
Oil or melted fat	Mint sauce
Green peas	

Skin the chops and trim away any excess fat. Brush them over with oil or melted fat and put them under a hot grill. Cook for a few minutes on one side, then turn the chops over, using two wooden spoons or a palette knife, and cook the other side. Continue to cook, turning them occasionally, and allowing about 8–10 minutes altogether. Decorate the end of each chop bone with a cut paper frill and serve them on a hot dish with green peas and new carrots, and mint sauce served as an accompaniment.

Pork chops must be grilled for 20 minutes at least, and are delicious served with fried apple rings or apple sauce.

Pork Chops Baked and Stuffed

Flatten the chops and trim them if necessary, lay them on a baking-dish and cover the lean part of each chop with a layer of sage-and-onion stuffing. Cover with greased paper and bake in a moderately hot oven (400° F.) until the lean is well cooked and the fat crisp and brown—about ½ hour. Serve with baked tomatoes and apple sauce.

Boiled Leg of Mutton and Caper Sauce

½ leg mutton
Boiling water
Salt and pepper
4 medium-sized carrots, turnips, and onions
Caper sauce

Wipe the meat. Have ready sufficient fast-boiling water to cover the joint completely, place it in the pan, and when the water again reaches boiling point, allow it to boil for a few minutes. Then add the seasoning and the vegetables, cut into quarters. Simmer gently until the joint is cooked, allowing 20 minutes to the lb. and 20 minutes over. When cooking is almost complete, prepare the caper sauce, using the liquid from the pot. Serve the meat on a hot dish, put the vegetables round and pour over the caper sauce.

Brown Stew

¾–1 lb. stewing steak
1 onion
2–3 carrots
A piece of turnip
A stick of celery
1 tablespoonful dripping
1 oz. flour
1 pint stock or water
Seasoning
A bouquet garni
Gravy browning, if necessary

Wipe the meat and cut into neat pieces. Peel the onion and cut into thin rings. Prepare the other vegetables and cut into rings or dice. Melt the dripping in a pan, place half the meat in the fat and fry quickly until it is lightly brown, then turn and fry on the other side; fry the rest of the meat. (If all the meat is put in the pan at once, it will cool down the fat and the frying will be very slow.) Lift the meat out on to a plate, re-heat the fat, add the onion, and fry for a few minutes until lightly coloured. Remove from the fat, then add the flour and fry until browned. Add the liquid gradually, season and bring to the boil. Put in the meat, vegetables, and bouquet garni, cover and simmer gently for about 2–2½ hours. If stewing in the oven, turn the contents of the pan into a casserole and allow to cook gently in a slow oven (325° F.) for 3–4 hours. Before dishing, remove the bouquet garni, re-season and, if necessary, add a few drops of gravy browning to colour. If fat meat is used, the stew sometimes becomes greasy; this can easily be rectified by blending 1 teaspoonful of flour with a little cold water, stirring it into the stew and re-boiling; the flour will then absorb the excess fat.

Brown stew can be varied by: (1) adding potato dumplings; (2) adding 1 tablespoonful of piquant sauce and a clove or garlic to sharpen the flavour. Potatoes can be cooked in the same pot as the stew; they should be peeled and placed whole on top of the stew and cooked for at least an hour. If available, 2–3 mushrooms, a few tomatoes, or a cupful of cooked beans may be added to enrich the flavour.

Irish Stew

1 lb. middle neck of mutton
2 lb. potatoes
2 large onions
Salt and pepper
Cold water
Chopped parsley

Prepare the meat by wiping thoroughly, removing the marrow and cutting into neat pieces. Cut the potatoes and onions into rings and place alternate layers in a pan, finishing with a layer of potato. Add salt and pepper and sufficient water to half-cover. Bring to the boil and simmer gently for about 2 hours, or until the meat and potatoes are tender.

Pile the meat, gravy, and some of the potatoes in the centre of a hot dish, placing the rest of the potatoes at either end of the dish. Sprinkle with a little chopped parsley.

Beef Olives

1½ lb. thick beefsteak
Veal forcemeat
Diced mixed vegetables
Seasoning
1 pint stock
Mashed potatoes
1 oz. flour

Cut the meat into slices about ¼ in. in thickness, and then into oblongs of about 2½ by 3 in. Spread with the veal forcemeat, roll up, and tie with string. Braise on a bed of vegetables in the seasoned stock until tender—about 1½–2 hours. Remove the string and serve the meat on mashed potato with some of the gravy (thickened flour) poured over.

Dry Curry of Beef

1 lb. frying steak
1½ oz. dripping
2 onions
1 small apple
1 dessertspoonful curry powder
1 tablespoonful chutney or other pickle
1 teaspoonful red-currant jelly
A squeeze of lemon juice
Rice

Cut the beef into even-sized pieces. Melt the fat and fry the chopped onions, apple, and curry powder. Add the meat, chutney, jelly, and lemon juice. Mix thoroughly and cook very slowly with the lid on until the meat is tender, stirring frequently. Serve with a border of rice.

Steamed Meat Roll

Suet-crust pastry
1 lb. beefsteak
1 onion or leek
1 carrot
Salt and pepper
Stock

Make the suet-crust pastry and roll it out. Mince the meat, onion or leek, and the carrot, season with salt and pepper, and moisten with a little stock. Spread this mixture on the pastry, moisten the edges with a little cold water, and roll up. Tie in a floured pudding-cloth, allowing room for the roll to swell, and steam for 3 hours. Serve with a good brown gravy sauce.

Cooked meat and vegetables may be used in the same way, and instead of steaming the roll it may be baked in a moderately hot oven for about 45 minutes and served with gravy sauce.

Sausage-meat Galantine

1 lb. sausages
1 or 2 rashers of bacon
Any pieces of cooked meat, etc. (if available)
1 tablespoonful chopped parsley
2 teaspoonfuls chopped onion or leek
½ teaspoonful mixed herbs
Pepper and salt
Stock or water

Skin the sausages and mince the bacon, and meat if used. Mix with the herbs and seasonings and moisten with a little stock or water. Form into a roll and tie in a floured cloth. Boil for 1 hour. Serve hot, with a good brown sauce and green vegetables. Serve cold, rolled in browned crumbs, with a green salad.

Braised Ham

½ a ham, either bottom or knuckle end
½ a carrot
1 turnip
1 onion
A bouquet garni
1 quart stock
3 sliced tomatoes
Mushrooms, if liked
½ pint rich brown sauce

Soak the ham for 12 hours at least, longer if possible. Place in a large pan with the carrot, turnip, onion, and herbs. Add just sufficient water to cover and simmer for 2½–3 hours, according to the size of the joint, then remove from the saucepan and peel off the brown skin. Place the meat in a braising-pan or strong deep saucepan, add the stock, tomatoes, and a few mushrooms, if available. Place in the oven, put on the lid, which should be tight-fitting, and cook for 1–1½ hours, the time depending on the size of the ham. Dish up, strain the stock, and reduce it to half-glaze by boiling. Then brush over the top. Add the brown sauce to the remainder, boil for a few minutes and serve as gravy.

Meat-and-bacon Roll

4 oz. minced raw meat
2 oz. minced bacon
2 oz. minced onion or leek
½ teaspoonful mixed herbs
1 teaspoonful chopped parsley
Salt and pepper
A little stock or gravy
8 oz. suet-crust pastry

Mix together the minced raw meat, bacon, and onion. Add the herbs and season well with salt and pepper, then moisten with a few tablespoonfuls of stock or gravy.

Make the pastry in the usual way. Roll into an oblong ¼ in. in thickness and spread to within ½ in. of the edge with the prepared filling. Moisten the edges and roll up as for jam roly-poly. Roll in greased paper. Tie in a cloth and steam for 2–3 hours. Serve with gravy or a good sauce.

Steak-and-kidney Pudding

8 oz. self-raising flour	¾ lb. stewing beef
½ teaspoonful salt	2 kidneys
3 oz. suet or cooking-fat	1 tablespoonful seasoned flour
Water to mix	

Grease a pudding-basin. Sieve the flour and salt and add the chopped suet (if cooking fat is used, rub into the flour until the consistency resembles that of fine breadcrumbs); mix with sufficient water to bind, and roll out into a round large enough to line the basin and cover the top. Prepare the meat by cutting into neat pieces and dipping in seasoned flour. Fill the basin, pour in a little water, damp the edges of the pastry, and draw up over the meat. Cover with a floured cloth or several layers of greaseproof paper, and boil or steam for 3–4 hours.

To dish, wrap the basin in a clean table napkin, and add a little boiling water to the pudding just before serving.

Blanquette of Veal

1 lb. veal (neatly cut up)	2 egg yolks
2 onions	2 tablespoonfuls cream
A bouquet garni	Juice of 1 lemon
White stock or water	Chopped ham, lemon, and parsley to garnish
2½ oz. butter	
2 oz. flour	

Put the veal, onions, and herbs in a stew-pan with enough white stock or water to cover. Simmer very gently until tender—1½ hours. Strain and keep the meat hot. Make a sauce with the butter, flour, and 1 pint of the stock. Cook well, then add the egg yolks, beaten with cream and lemon juice, and reheat carefully, but do not re-boil. Pour over the veal and garnish with chopped ham, lemon fans, and chopped parsley.

Veal Cutlets (or Escalopes)

1 lb. fillet of veal	¼ pint brown or tomato sauce
Lemon	Rolls of bacon or cooked green peas to garnish
Seasoning	2 oz. butter or dripping
Egg and breadcrumbs	
Mashed potatoes	

The meat should be cut in slices about ¼ in. in thickness. Trim it and cut it in neat rounds or oval-shaped pieces, beating it out if too thick in parts. Rub each piece over with a cut lemon and sprinkle lightly with pepper and salt. Then egg and breadcrumb the cutlets, pressing the crumbs well on with a broad-bladed knife, and re-shaping the cutlets neatly on a board. Lay them on a tin or dish with a double fold of kitchen paper under them, and let them rest for a short time to dry.

Meanwhile, prepare ¼ pint of brown or tomato sauce and some nicely mashed potatoes. Also make ready a few little rolls of thinly sliced bacon, fix these on a skewer, and cook them in the oven or under the grill for a few minutes.

To cook the cutlets, melt the fat in a frying-pan. When smoking hot, place in the cutlets. Fry them rather slowly, first on one side and then on the other, until they are well browned. Allow from 10–12 minutes for the cooking, as veal must not be underdone; lift out and drain on the paper. Arrange the potato in a circle on a hot dish, and place the cutlets along the top, one leaning against the other. Fill up the centre with the rolls of bacon, or with nicely cooked peas if preferred, and pour the sauce round. Serve cut lemon separately.

Brain Cakes

1 calf's brain	Salt, pepper, and nutmeg
1 oz. butter or margarine	1 egg yolk
1 oz. flour	Egg and breadcrumbs for coating
¼ pint milk	Fat for frying
½ teaspoonful chopped parsley	Parsley to garnish
2 oz. breadcrumbs	White sauce

Cover the brain with cold water, add a teaspoonful of salt, and bring to the boil. Skim, then boil gently for 10 minutes. Strain, leave to get cold, and then cut into small pieces. Melt the butter, stir in the flour, gradually add the milk, then stir until the mixture boils and thickens. Add the yolk of egg and stir for a few minutes over a low heat without boiling. Let the mixture get cold, then divide it into little cakes: sprinkle these with flour, brush with beaten egg, and toss in breadcrumbs. Fry in smoking hot fat until crisp and golden-brown, garnish with parsley and serve with white sauce or other good sauce.

Stuffed-liver Casserole

½ lb. liver	¾ pint stock or water
2 oz. fat bacon	Seasoning
½ oz. flour	

For the Stuffing

8 oz. mashed potatoes	½ oz. margarine
½ teaspoonful chopped parsley	Seasoning
	1 small finely chopped onion

Wash and dry the liver and cut into thin slices. Cut the bacon into slices slightly larger than the liver pieces. Blend the flour with the liquid and season well.

Make the stuffing by thoroughly blending all the ingredients together. Place a little stuffing on each slice of liver and roll up, then roll this in a piece of bacon. Place the rolls in a greased casserole and half-cover with the blended flour and stock. Cover and bake in a moderately hot oven (400° F.) for ¾–1 hour, until the liver and bacon are tender. If desired, the lid may be removed 10 minutes before cooking is completed, to brown the bacon.

Stewed Ox-tail

1 ox-tail	About 1 quart stock or water
1 oz. dripping	Salt and pepper
Flour	2 oz. flour
1 onion	A few drops of lemon juice or vinegar
Flavouring vegetables (carrot, celery, turnip)	Diced carrot and turnips to garnish (optional)
Herbs, cloves, peppercorns	
1 meat cube	

Cut the tail into pieces and trim off any excess fat. Melt the dripping, lightly dredge the pieces of tail in flour, and fry them and the onion until golden-brown. Add the flavouring vegetables cut into small pieces, the herbs and spices tied in muslin, the meat cube, and stock or water to cover. Season, cover closely, and simmer gently until tender (about 3–4 hours, or longer if necessary). Remove the bag of herbs and skin off all fat; if preferred, leave to stand overnight and remove the fat when cold.

Blend 2 oz. of flour with a little stock and add it to the stew, stirring while it comes to the boil. Add more seasoning, if necessary, and a few drops of lemon juice or vinegar. Arrange the meat and vegetables on a hot dish and strain the sauce over, garnishing, if liked, with diced carrot and turnip cooked separately.

Boiled Ox Tongue

To Prepare and Pickle: Wash and scrape the tongue thoroughly until all slimy substance is removed. Rinse in cold water and dry. Cut off some of the gristle and root part. Rub all over with coarse salt and leave overnight to drain. Prepare a wet pickle as follows:

1 lb. block salt	1 oz. saltpetre
6 oz. brown sugar	1 gallon water

Boil for 5 minutes keeping the surface skimmed, then drain into a large basin and leave until cold. Strain over the tongue, completely covering it with the liquid. Allow to soak for at least a week.

Soak the pickled tongue in cold water for several hours. (If a smoked tongue is used, it will need 12 hours soaking.) Wash the tongue, skewer into shape, put into lukewarm water, bring slowly to the boil, and skim. Add flavouring vegetables and peppercorns, and simmer the tongue very gently until tender: a 6-lb. tongue will need to simmer for 3–4 hours. When tender, take out the tongue, plunge into cold water so that the skin will come off easily, and skin it very carefully. Slip out any bones in the root and cut off remaining gristle. Roll the tongue while still hot into a round cake-tin, fitting it in tightly. Add a little jellied stock, put a weighted cover on top and leave to set for several hours.

Fried Sweetbreads

1 sweetbread	Fat for frying
Stock or water	Lemon and parsley to garnish
Salt and pepper	
Egg and breadcrumbs	

First wash the sweetbread and soak in cold water for 1–2 hours, changing the water occasionally. Put into a pan and blanch, then cover with cold water and remove with the fingers any veins, fat, or skin that will come away without damaging the sweetbread. Put into a pan with a little stock or water and simmer gently for 25–30 minutes. Drain and press between two plates until cold. Slice the sweetbread neatly, season it, and egg-and-crumb the slices. Fry until golden-brown, then drain and serve garnished with cut lemon and parsley.

Tripe and Onions

2 Spanish onions	½ pint milk
1½ lb. prepared tripe	Seasoning
1 oz. butter	A pinch of nutmeg
1 oz. flour	Toast
½ pint tripe liquor	

Peel the onions and cook them together with the tripe until both are tender. Then drain, reserving the liquor. Cut the tripe in pieces and chop the onions. Melt the butter in a fireproof casserole, mix in the flour, and then add the tripe liquor, a little at a time. Stir until boiling, add milk, seasoning, onions and tripe, and simmer all together for about 15 minutes, stirring occasionally. Serve in the casserole, garnished with toast cut in pieces.

POULTRY

The selection of poultry is of prime importance. When buying look for a plump bird with a smooth skin. For roasting the bird must have a flexible breast bone and smooth legs with short spurs. Most poultry is sold ready for the table; if, however, it has not been prepared it should be hung by the feet, somewhere cool, so that air can circulate round it. It should not be hung more than two to three days, according to weather conditions. The plucking is best carried out directly after killing, whilst the bird is still warm, then singe with a lighted taper. Remove the sinews from the legs, cut off the head, and draw after hanging and when required. The liver, gizzard, heart, and neck are used for making stock. Prepare the liver by removing the gall bladder, and the gizzard by cutting through to remove the "bag of grit". Fowls and turkeys are usually stuffed at the neck end, and geese and ducks at the tail end. After stuffing, truss the bird to keep it a good shape. The appropriate stuffings and accompaniments are as follows:

Turkey.—Sausage, celery, chestnut, or other forcemeat. Serve with gravy, bread sauce; sausages, bacon rolls, or cranberry sauce.

Chicken.—Forcemeat stuffing. Serve with gravy, bread sauce, sausages, fried crumbs, bacon rolls.

Duck—Sage-and-onion stuffing. Serve with gravy, apple sauce, and orange salad.

Goose.—Sage-and-onion stuffing. Serve with gravy, and apple sauce.

Guinea Fowl.—Serve with watercress, gravy, and orange salad. For roasting times see S6.

Chicken Casserole

1 chicken	Salt and pepper
1 oz. seasoned flour	A bouquet garni
1 onion	½ lb. mushrooms *or*
Dripping	½ lb. tomatoes
1 pint stock or water	

Joint the chicken, cut into convenient-sized pieces, and dip in seasoned flour. Cut up the onion finely and fry until golden in the hot dripping. Brown the chicken and put into a casserole with the onions. Stir the rest of the seasoned flour into the dripping and fry until brown, then add the stock or water and stir until boiling. Season well. Pour into the casserole over the chicken and add a bouquet garni and the roughly chopped mushrooms or tomatoes. Put on the lid and cook in a moderate oven (375° F.) for about 1½ hours, or until the legs of the chicken are tender when pierced with a fork or skewer. Remove the bouquet garni and serve.

Chicken Maryland

1 prepared chicken	White breadcrumbs
Seasoning	Dripping
Flour	Milk and stock mixed
1 egg	¼ lb. sliced mushrooms

Simmer the giblets and neck for stock. Season the jointed bird, dip in flour, then in beaten egg. Roll it in the crumbs and put in a greased tin. Roast in a moderately hot oven (375° F.), basting occasionally, until tender. Make a sauce by stirring a tablespoonful of flour into some of the fat left in the tin, and adding milk and stock. Simmer the mushrooms in the sauce. Serve the chicken with the sauce poured around.

Chicken Fricassée

1 chicken	1½ oz. flour
1 onion	A squeeze of lemon juice
1 stalk of celery	
A bouquet garni	A little "top of milk" if available
1½ pints stock or water	
Salt and pepper	Parsley
2 oz. margarine	Bacon rolls

Joint the bird, cut into convenient-sized pieces, and put into a pan with the sliced onion, chopped celery, bouquet garni, liquid, and seasoning. Cover the pan and simmer gently for about 1½ hours, or until the chicken is tender. Melt the margarine in another saucepan and stir in the flour. Gradually add about 1 pint of the chicken liquor and a squeeze of lemon juice. When boiling stir in a little "top of the milk," if available and season. The sauce should be of a coating consistency. Arrange the cooked chicken in a hot dish, pour the sauce over, and garnish with parsley and small rolls of bacon.

Chicken Galantine

Allow 12 oz. sausage-meat, some slices of ham (or tongue or bacon), and two hard-boiled eggs to each chicken. Spread some of the sausage-meat on the boned bird, and arrange slices of the ham and the sliced eggs on top. Season, and cover with the rest of the sausage-meat. Fold in both ends of the boned chicken and roll it up tightly. Tie in a clean cloth and simmer in stock for 2 hours. Place the galantine on a dish and press it down by putting a weighted dish on top. When it is cold brush the surface with glaze and decorate with piped butter and aspic jelly.

Devilled Turkey Legs

Chop off any unsightly length of bone and score the flesh of the legs deeply with a sharp knife, both round and across. Brush with melted butter.

Mix on a plate 1 teaspoonful each of French and English mustard, 2 of finely chopped chutney, a pinch of ground ginger, pepper, salt, Cayenne pepper, and browned breadcrumbs. Spread this mixture over and into the cuts, put the turkey legs aside for an hour, then cook under a very hot grill until crisp and brown. Serve quickly, garnished with water-cress. Pats of butter and some piquant sauce may be served separately.

Braised Duck

1 duck	A bouquet garni
Dripping	Salt and pepper
2 rashers of bacon	¾ pint stock
1 carrot	1 orange
1 onion	1 oz. flour
2 sticks celery	Watercress
A piece of turnip	

Joint the duck, cut into convenient-sized portions, and fry in a little dripping until brown. Dice the bacon, carrot, onion, celery, and turnip and put at the bottom of a stewpan or casserole. Add the *bouquet garni* and the fried pieces of duck. Season and add the stock, which should just cover the duck. Cover and cook on top of the stove or in a moderately hot oven (400° F.) until tender—this will take about 1½–2 hours. Put the pieces of duck on to a hot-plate. Strain the liquor and add the grated orange rind and juice of half the orange. Thicken the sauce with blended flour and pour over the duck. Garnish with watercress and pieces of orange.

Casserole of Pigeons

2 pigeons
1 tablespoonful flour
Pepper and salt
A piece of ham or bacon
1 oz. dripping
Piece of turnip, sliced
1 stalk of celery, sliced
1 onion, sliced
¾ pint stock or water
Bunch of herbs, tied in muslin

Prepare the pigeons, cut in halves, and toss in seasoned flour. Dice the ham or bacon and fry until lightly browned, then remove it from the pan. Add the dripping to the pan and fry the pigeons in this until lightly browned, and then remove from the pan. Add the vegetables and sauté for several minutes. Then add the flour, stir in the stock and bring to the boil, stirring. Return the pigeons and the bacon, and add the bunch of herbs (tied in muslin). Cover and simmer gently until the pigeons are tender (about 2 hours), or put into a casserole and cook in a slow oven. Remove the herbs and add more seasoning if necessary. Place a border of mashed potatoes round a hot dish, arrange the pigeons and vegetables in the centre, and pour the sauce over, or, if cooked in a casserole, it may be served without dishing.

GAME

All wild birds and animals protected by law during certain seasons of the year are known as game. The most common of these are pheasants, partridges, grouse, wild duck, hares and deer. Less commonly eaten in this country are snipe, plover, woodcock, quail, and ptarmigan. The game seasons are roughly from August, September, or October until December, February, or March, although it is now possible to buy frozen or imported game out of season.

Game birds should be hung for a week at least before being plucked and drawn. If cooked too soon game is tough and lacks flavour. The actual length of time for hanging can be judged only by individual taste, but as a guide the bird should be ready when the tail feathers come away easily. Small birds such as snipe and woodcock require less hanging time, and should be roasted undrawn on a piece of toast which is served with the bird.

Directions for roasting are given in the previous chapters, but game can be served with the following accompaniments.

Pheasant, *Partridge*, *Grouse*, *Ptarmigan*	Gravy, bread sauce, fried breadcrumbs, and game chips
Snipe, *Plover*, *Woodcock*, *Quail*	Gravy, fried breadcrumbs, game chips
Wild Duck	Gravy, orange salad, game chips

Pheasant Casserole

1 pheasant
Seasoned flour
Fat for frying
4–6 oz. mushrooms
Salt and pepper
2 rashers of chopped bacon
Stock
A little port (optional)
Chopped parsley

Joint the bird and dip the pieces in the seasoned flour. Heat the fat in a frying-pan and fry the pieces of pheasant until they are golden-brown, then put them in the casserole, with the sliced mushrooms, the chopped bacon, salt and pepper, and sufficient stock to half-cover the pheasant. A little port wine may be added with the stock, if desired; cook gently in a moderate oven (350° F.) for about 1½ hours. Just before serving, sprinkle the surface with chopped parsley. Serve with creamed or chipped potatoes and orange salad.

A Salmi of Partridge

Partridges
A little butter
Carrot
Onion
1–2 shallots
1 tablespoonful flour
Little white wine
Stock
1 tomato
A few mushrooms
Croûtons of fried bread

This can be made with either cooked or uncooked birds. If the latter, they should be roasted and left rather underdone, as they will finish cooking in the sauce. Cut each partridge into two or three pieces, according to its size. Remove the skin and the larger bones of the carcase, arrange the pieces in a casserole, and cover whilst making the sauce. Chop up the scraps, put them into a frying-pan with a little butter, a few small pieces of carrot and onion, and one or two shallots. Fry until brown, then sprinkle with about 1 tablespoonful of flour and brown that also. Moisten with a little white wine and stock, and add a tomato cut in pieces. Cover and cook slowly for 1 hour. Meanwhile cook a few fresh mushrooms, putting the trimmings in the sauce. When the sauce is ready, strain it over the pieces of partridge and let them heat thoroughly, but without boiling. In a salmi the sauce should be thick and velvety and the joints of game should seem to have been cooked with it, and must not appear to be swimming in gravy. Garnish with the mushrooms and some croûtons of fried bread.

Game Croquettes

¾ lb. cold cooked game
¾ lb. creamed potatoes
Seasoning
Beaten egg
Breadcrumbs
Fat for frying
¼ lb. mushrooms
Game chips
Parsley or watercress

Remove any bones or pieces of skin from the cold cooked game and mince the flesh finely. Place in a bowl with the creamed potatoes and seasoning, and mix well. Form the mixture into croquettes, coat them with beaten egg and roll them in breadcrumbs. Heat the fat in a pan until smoking hot, then fry the croquettes until they are golden-brown. Drain them carefully, and serve them at once in a hot dish, with grilled or fried mushrooms and game chips. Garnish with parsley or watercress.

Stewed Venison

(Use the shoulder, breast, and neck for stewing.)

1 lb. vension
1½ oz. flour
Salt, pepper, nutmeg
1 onion
1½ oz. dripping
Stock
Bunch of herbs, tied in muslin
1 dessertspoonful vinegar

Cut the venison in joints and toss in the seasoned flour. Slice the onion. Fry the meat and onion in the hot fat until lightly browned, then stir in any remaining flour, and brown, before adding the stock, bunch of herbs, and vinegar. Cover, and stew gently in the oven or on the top of the stove until tender (2–3 hours). Serve with stewed celery or a green vegetable.

Jugged Hare

1 hare
1–2 oz. dripping
1 rasher of bacon
1½ pints stock or water
1½ oz. flour, blended with a little stock
1 onion stuck with 2 cloves
Seasonings
Bunch of herbs tied in muslin
Small bay leaf tied in muslin
4 peppercorns tied in muslin
Small blade mace tied in muslin
1 teaspoonful red-currant or other sharp jelly
1 glass port or other red wine
Force meat balls

Skin and paunch the hare, reserving the blood and saving the liver, heart, and kidneys. Wipe the hare and cut into joints. Heat the dripping in a casserole and fry the joints in it with the bacon. When the meat is lightly browned add stock to cover and stir in the blended flour, the onion, seasonings, and herbs.

Cover and cook very gently in a moderate oven, or on top of the stove, until tender (about 3 hours).

A few minutes before serving remove the onion and herbs. Stir in the strained blood, the red-currant jelly, and the wine. Reheat without boiling, and serve garnished with forcemeat balls.

Roast Stuffed Rabbit

1 rabbit
Fat bacon
Dripping
½ oz. flour
½ pint stock or water
Bread sauce

For the Stuffing

4 oz. breadcrumbs
2 oz. chopped suet
½ teaspoonful thyme
A little grated lemon rind
Salt and pepper
A squeeze of lemon juice
A few drops of piquant sauce
Beaten egg or milk to mix

Prepare the rabbit. Wash the heart, liver, and kidneys, put in cold water and bring to the boil.

Strain, chop finely, and mix in a large basin with the other stuffing ingredients. Stuff the rabbit with forcemeat and sew up, leaving the ends of the string loose so that it can be removed after cooking. Cut the sinews in the hind legs at the thigh, bring legs forward and press closely against body; bend forelegs in the same way, and keep all in position with two fine metal skewers or with string. Tie a piece of fat bacon on the back and cover with greased paper.

Roast for about 1–1½ hours, basting every 15 minutes. A quarter of an hour before it is ready remove the paper and bacon, baste well, and remove skewers and string. Drain the surplus fat from the tin, add the flour, brown it, and add the stock or water to make a thick gravy; boil this for 5 minutes and strain it round the rabbit. Serve with bread sauce.

Rabbit Pie

1 small rabbit	2 tablespoonfuls chopped parsley
2–3 potatoes	¼ teaspoonful mixed herbs
1 onion	1 bay leaf
1 piece of fat bacon	Stock or water
Salt	8 oz. short-crust pastry
4 peppercorns (crushed)	

Wash the rabbit thoroughly and cut into neat joints, putting aside the head and the ribs for stock. Prepare and slice the potatoes and onion. Fill a pie-dish with alternate layers of rabbit, bacon, and vegetables, sprinkling each with seasonings and herbs. Put in the kidney and heart of the rabbit, the bay leaf, and sufficient liquid to come half-way up the dish. Cover with pastry, making a hole to let out the steam, and decorate with pastry leaves. Bake in a hot oven (450° F.) until the pastry is set and lightly browned, then reduce the heat and cook until meat and vegetables are tender—about 1½ hours in all. Fill up with stock and serve hot.

EGG AND CHEESE COOKERY

Both egg and cheese are rich in protein and can be cooked in many different ways to provide a satisfying main course. Cheese should be carefully cooked, otherwise it may become tough and indigestible, grate it finely and avoid boiling cheese sauces. The addition of dry mustard to a cheese dish helps to bring out the flavour.

Plain Omelet

½ oz. butter or margarine	3 eggs
	Pepper and salt

Melt the fat over a brisk heat and tilt the pan so as to allow the sides to become greased. Whisk up the eggs just sufficiently to mix the yolks and whites thoroughly together, and add seasoning. When the fat is beginning to brown, turn the eggs into the pan. Tilt the pan backwards and forwards and gather the mixture in from the sides as it cooks. When it is thick and creamy pour out the egg mixture evenly over the surface of the pan. Allow it to set for a second or two, then tilt the pan away from you and fold the omelet in three, forming a roll in the pan. Brown it slightly on the underside if preferred. Turn the omelet out on to a heated oval dish. Garnish and serve at once.

Ham Omelet

1 oz. butter	4 eggs
2 tablespoonfuls cooked ham	Pepper and salt

Melt the fat in the omelet pan, add the diced ham, and fry until lightly browned. Beat the eggs, season, pour them into the pan over the ham. Allow it to set for a second or two, then tilt the pan away from you and fold the omelet in three, forming a roll in the pan. Brown it slightly on the underside if preferred. Turn the omelet out on to a heated oval dish. Garnish and serve at once.

Soufflé Omelet

3 eggs	3 tablespoonfuls water or milk
Seasoning	½ oz. butter

Separate the egg yolks and whites. Beat the yolks with a wooden spoon until pale and creamy, add seasoning and liquid and beat again. Whisk the whites very stiffly. Now gently melt the butter in the omelet pan, without browning. Carefully fold the egg whites into the yolk mixture, avoiding over-mixing. Grease the sides of the pan with the melted fat and pour in the egg mixture. Cook over a moderate heat until golden-brown on the underside, then place the pan in a moderate oven (350° F.) or under the grill and lightly brown the top of the omelet. Run a spatula gently round the edge and underneath the omelet to loosen it, then mark it in halves and double it over. Turn it gently on to a hot plate, garnish, and serve at once.

Baked Eggs

Use individual oven-proof dishes of glass or china (ramekin cases) for this dish. Place them on a baking-sheet with a knob of butter in each dish and put in moderately hot oven (400° F.) for 1–2 minutes. When the butter is melted, break a fresh egg into each dish, season with salt and pepper, and return to the oven until just set—5–8 minutes. Serve at once.

Scrambled Eggs

2 tablespoonfuls milk	Salt and pepper
½ oz. butter	Buttered toast
2 eggs	

Heat the milk and the butter in a strong saucepan, but do not boil. Beat the eggs, add salt and pepper, and pour into the saucepan. Stir over a gentle heat until the mixture begins to thicken, then remove from the heat and stir until creamy. Pile on to hot buttered toast and serve immediately.

Stuffed Eggs

4 hard-boiled eggs	1 teaspoonful mayonnaise
½ oz. butter or margarine	A little chopped parsley
	Salt and pepper

Cut the eggs in half crossways and remove a small piece of white from the bottom of each, so that they stand firmly. Mix the yolks with the fat, mayonnaise, parsley, and seasoning, and pipe into the cases. Serve with salad and a good mayonnaise.

Scotch Eggs

½ lb. sausages or sausage-meat	Breadcrumbs
3–4 hard-boiled eggs	Fat for frying
2 teaspoonfuls seasoned flour	Parsley
A little piquant sauce	Tomato sauce
Beaten egg	Croûtons of fried bread (optional)

Remove the skins from the sausages and shell the eggs. Pass the eggs through the seasoned flour. Add a few drops of piquant sauce to the sausage-meat and divide equally into 3–4 pieces, according to the number of eggs. Cover each egg with the sausage-meat, doing this as evenly as possible to keep the egg a good shape. Brush over with beaten egg, toss in breadcrumbs, and fry in deep fat from which a very faint blue smoke is rising. As the sausage-meat is raw, it is essential that the frying should not be hurried unduly, and for this reason the fat must not be too hot. When the eggs are golden-brown in colour, remove from the fat and drain. Cut in half width-ways, garnish with a small piece of parsley, and serve with tomato sauce.

The eggs may be placed on croûtons of fried bread.

Welsh Rarebit

4 oz. cheese	A pinch of Cayenne pepper
½ teaspoonful dry mustard	A little milk
	Hot toast

Grate the cheese and add the mustard, pepper, and enough milk to moisten. Melt this in a double boiler or over gentle heat until it is creamy, and pour on to hot toast.

Macaroni Cheese

2 oz. macaroni	Salt and pepper
1 oz. fat	2–3 oz. grated cheese
1 oz. flour	Brown breadcrumbs
¾ pint milk	

Boil the macaroni in the usual way and drain. Melt the fat, add the flour, and cook for a minute.

Gradually add the milk and stir until it boils. Add the salt and pepper and the grated cheese, reserving a little. Add the cooked macaroni and pour into a greased au gratin dish. Sprinkle with brown crumbs and the rest of the cheese, and brown under a hot grill.

Cheese Pudding

6–8 slices bread and butter	2 teaspoonfuls piquant table sauce
2 eggs	4 oz. grated cheese
A little made mustard	1 pint milk
Salt and pepper	1 oz. breadcrumbs
1 chopped onion	

Cut the slices of bread into neat pieces and arrange in a pie-dish. Break the eggs in a basin and add the seasonings, finely chopped onion, and the sauce. Beat well and add the cheese, reserving about a quarter of it for the top. Stir in the milk, pour the mixture over the bread and butter in the pie-dish, and allow to soak for about 15 minutes before baking. Mix the remaining cheese and the breadcrumbs together, sprinkle over the top of the pudding and bake in a moderate oven (350° F.) until the mixture sets.

Cream-cheese Tartlets

3–4 oz. short-crust pastry	1 egg
1 oz. cream cheese	Pepper and salt
½ pint thick white sauce	1 oz. Parmesan cheese
½ teaspoonful piquant sauce	Paprika pepper

Line a number of small tartlet tins with the short-crust pastry. Using a fork, beat together the cream cheese, white sauce, piquant sauce, yolk of egg, and a little pepper and salt to make a creamy consistency. Beat the white of egg until stiff, and fold gently into the mixture. Three-parts fill the lined tartlet tins with the mixture and bake in a moderately hot oven (400° F.) for about 15–20 minutes. Before serving, sprinkle a little grated Parmesan cheese on top and dust with paprika pepper.

Hot Cheese Soufflé

3 eggs	½ pint milk
1 oz. butter	3 oz. grated cheese
1 oz. flour	Salt and pepper

Separate the eggs. Melt the butter and stir in the flour, gradually add milk and bring to boil, stirring. Cool slightly; add cheese, seasoning, and egg-yolks one by one, beating well. Fold in the very stiffly beaten egg-whites, and put mixture into a prepared case. Bake in moderately hot oven (400° F.) about 30 minutes, till well risen and brown. Serve at once.

VEGETABLES

Vegetables, especially greens, should be used as soon as possible in order to retain the maximum food value. When storage is inevitable keep them in a cool, airy place. Prepare the vegetables according to type, and cook by boiling, steaming, braising, baking, or frying (see previous chapter).

Potatoes

Boiled.—Allow these about 20 minutes to cook. For new potatoes a sprig of mint is usually added to the water. Serve glazed with a little margarine.

Steamed.—Allow about 30–40 minutes, according to size; then either serve the potatoes mashed or glaze with margarine and sprinkle with parsley.

Creamed.—Boil or steam some potatoes until tender, and sieve them or beat well with a fork, adding margarine, milk, and pepper. Serve hot, sprinkled with parsley.

Roast.—Cook these in dripping round the meat, or in a separate tin; baste occasionally, and allow about ¾–1 hour. The potatoes are sometimes par-boiled first.

Fried.—Cut the peeled potatoes into chips or rings and dry them in a tea-towel; then fry in smoking-hot fat to cover them completely a few at a time until golden brown. To make game chips slice the potatoes wafer-thin.

Duchesse Potatoes

1 lb. hot cooked potatoes	"Top" of milk
1 oz. margarine	Salt and pepper
1 egg	Beaten egg to glaze

Sieve the potatoes. Melt the fat in a pan, add the potatoes, and when warm add the beaten egg, about a tablespoonful of creamy milk, and seasoning to taste. Turn on to a floured board and divide into small squares. Place these on a greased baking-tin, brush over with beaten egg, and brown in a hot oven (450° F.). If preferred, force the mixture in the form of rosettes, using a large star pipe. Glaze with egg and bake as above.

Potato Salad

Lettuce	1 tablespoonful chopped celery
½ lb. diced cooked potatoes	1 tablespoonful chopped raisins
1 chopped onion	Mayonnaise
1 tablespoonful chopped parsley	

Arrange the lettuce-leaves in a dish. Mix all the other ingredients together and arrange on the lettuce.

Asparagus

Cut off the woody end of the stalks and scrape the white part lightly, removing any coarse spines Tie in bundles, and place upright in a saucepan of boiling salted water. Boil for 10 minutes, then lay flat and continue cooking until tender—a further 10–15 minutes. Drain very well and untie the bundles before dishing. Serve with melted butter (or margarine) or with Hollandaise sauce.

Asparagus may also be served cold, with a vinaigrette dressing or with mayonnaise.

Aubergine or Egg Plant

Egg plants should be of uniform purple colour, firm, smooth, and free from blemishes. To prepare them, cut off the stem and calyx, and wipe over. For some dishes the Egg Plants are required to be peeled; for others the skin is left on. They are usually stuffed and baked, sautéed, or fried.

Beans (Broad)

Shell, and cook in boiling, salted water until tender—20–30 minutes. If liked, serve with parsley sauce.

Towards the end of the season the skins of the beans may be very thick and tough—if this is the case it is well worth removing them before cooking.

When very young and tender, that is, when the pods are only a few inches long and the beans inside very small, the whole pods may be cooked and served, and these make a very delicious dish.

Beans (French and Runner)

Head, tail, and string the beans, and slice them diagonally. Cook in boiling salted water until tender—15–20 minutes, skimming if necessary. Drain well, then toss with salt and pepper and a knob of butter before dishing.

Young beans may be cooked whole if preferred.

Cold cooked French or runner beans are a useful ingredient in salads and hors d'œuvre.

Creamed Beetroot

1 large or 2 small beetroot	Salt and pepper
1 oz. butter	2 teaspoonfuls vinegar
1 oz. flour	Grated horseradish, if liked
½ pint milk	

Cook the beetroot very carefully, preserving its red colour. Skin, and cut into dice. Melt the butter in a pan, and mix in the flour. Add the milk by degrees, and bring to the boil, stirring continuously. Boil for 2–3 minutes, and then add the seasoning and vinegar. Add the cubes of beetroot to the sauce, and heat until the beet is hot through and the sauce coloured pink. Dish and serve at once, sprinkle, if liked, with a little grated horseradish.

Brussels Sprouts and Chestnuts

Brussels sprouts are frequently cooked with chestnuts. The sprouts should be prepared in the usual way and the shell removed from the chestnuts. Put both in boiling water and boil hard for 10 minutes, then strain both free from moisture, and remove the thin brown skin from the chestnuts. Melt 2 oz. butter to about 1 lb. chestnuts and Brussels sprouts, and stew them in the butter until both are thoroughly tender—about 15 minutes. Serve very hot.

Scalloped Cabbage

1 quart shredded cabbage	4 oz. diced or shredded cheese
½ pint well-seasoned white sauce	1 tablespoonful grated cheese

Shred fine white cabbage into ribbons, making 1 quart. Cook until tender in boiling salted water, drain well, and put in a greased baking-dish. To white sauce, made with ½ milk and ½ liquor from the cabbage, add the diced or shredded cheese. Cook gently until the cheese is melted and whip together until smooth. Pour the sauce over the cabbage, stir together lightly, sprinkle with the tablespoonful grated cheese, and brown in a very hot oven (425° F.) or under the grill.

Braised Carrots

1 lb. carrots	A pinch of sugar
1½ oz. butter	Salt and pepper
½–¾ pint brown stock	Chopped parsley

Prepare the carrots and cut lengthways into neat, even slices, or leave whole if young. Put into a pan of cold water, bring to the boil and strain. Heat the butter and fry the carrots golden-brown. Add half the stock, sugar, and seasoning, and cook gently for ½ hour, until tender, basting occasionally and adding the rest of the stock if required. Serve on a hot dish with a little of the liquor poured round and sprinkle with chopped parsley. Braised carrots are excellent with meat stews.

Cauliflower with Cheese Sauce

1 large or 2 small cauliflowers	Seasoning
2–3 oz. grated cheese	Slices of gherkin
¾ pint white sauce	A few capers
	A few mint leaves

Cook and drain the cauliflower and put it into an *au gratin* dish, reserving some of the best flower pieces for garnish. Add the cheese to the white sauce, keeping some cheese to sprinkle over the finished dish, if desired. Season the sauce, pour it over the vegetable, and garnish the dish with the reserved pieces; arrange the gherkin slices and capers to resemble flowers, adding the mint leaves.

To make cauliflower *au gratin*, mix pieces of cauliflower with sauce and pour into the dish. Sprinkle with cheese and brown crumbs, and brown in a hot oven (425° F.) or under the grill.

Braised Celery

Prepare the celery as usual and fry in a little dripping until lightly browned. Add salt and pepper and sufficient stock to half-cover. Cover closely with a lid, and cook gently until tender. Lift the celery on to a hot dish and boil the liquor until of a glazing consistency. Pour over the vegetables and sprinkle with chopped parsley.

Corn on the Cob

Pick the cobs when they are plump and well formed. Homegrown cobs may ripen to a pale golden yellow, but they are very good to eat when still green. Cook as soon after picking as possible.

Remove the outside leaves, leaving on the inner sheath. Put into boiling salted water and cook until tender; this will take about 12 minutes for fresh young cobs, or up to 30 minutes for older cobs. Drain, remove the sheath, and serve very hot, with butter (or margarine), pepper, and salt.

Stuffed Cucumber

1 large straight cucumber	¼ pint Espagnole sauce
¼ lb. chopped ham or sausage-meat	Croûtons of fried bread
Seasoning	Rounds of ham and truffle

Skin the cucumber, cut in 2-in. pieces, and take out the seeds with a round cutter or small vegetable knife. Season the meat, add one tablespoonful of the sauce, and pile into the prepared rounds. Braise slowly for about 20 minutes. Dish on croûtons of fried bread, put on rounds of ham and truffle as a lid, and pour Espagnole sauce (*see* S21) round.

Baked Stuffed Marrow

1 small marrow	1 tomato or a little tomato sauce
½ lb. onions	½ teaspoonful sage
¼ lb. scraps of meat (or liver, sausage, bacon, ham, etc.)	Salt and pepper
4 oz. dry bread (soaked and squeezed)	A little dripping
	Gravy or tomato sauce

Cut a wedge-shaped piece off the top of the marrow and scoop out all the seeds: there is no need to peel the marrow. Prepare and chop the onions, put into a basin with the minced meat (or bacon, ham, etc.), the soaked bread, sliced tomato or sauce, and the sage; season well with salt and pepper. Mix well together and fill into the marrow, then replace the lid. Grease a fireproof dish with dripping, put in the marrow, cover, and bake in a moderate oven (350° F.) until tender—approximately 1 hour. Serve with gravy or tomato sauce.

Stewed Mushrooms

1 lb. mushrooms	1 oz. flour
¾ pint milk	Salt and pepper
1 oz. margarine	Toast

Peel the mushrooms and cut into quarters. Add to the milk and bring to the boil. Melt the fat and add the flour. Gradually add the milk from the mushrooms, stirring until the mixture thickens. Season and pour over the mushrooms. Cover and simmer gently for 15–20 minutes. Serve with toast.

Stuffed Onions

Even-sized onions	Chopped parsley
Savoury cheese stuffing	Sauce or gravy
A little margarine	

After removing the papery outside skins, boil the onions for 30–40 minutes, according to size—do not allow them to become soft. Scoop out the centre portion with a small spoon or pointed knife. Fill the cavity with grated cheese mixed with some sieved dry mustard, breadcrumbs, and a little white sauce; minced bacon, breadcrumbs, and finely chopped sage or any other suitable filling may also be used. Place in a greased fireproof dish, dot the tops with shavings of margarine and bake in a hot oven (425° F.) for about ½ hour, until tender. Sprinkle the top of each stuffed onion with parsley and serve with a good white sauce, a tomato sauce, or gravy.

Seakale

Wash well, cut off the ends, and tie into neat bundles. Cook in boiling salted water to which a squeeze of lemon juice has been added (this is to preserve the white colour) until tender—20–30 minutes. Drain well, remove the string, and serve on toast, coated with a good white or Béchamel sauce. Seakale may also be braised or served *au gratin*. Cold, it may be served with vinaigrette dressing or added to a mixed salad.

Spinach

Wash well in several waters to remove all grit, and strip off any coarse stalks. Pack into a saucepan with only the water that clings to it. Heat gently, turning it occasionally, then bring to the boil and cook gently until tender—about 15 minutes. Drain thoroughly, and reheat with a knob of butter and a sprinkling of salt and pepper. If liked, the spinach may be sieved and one or two tablespoonfuls of white sauce, "top of the milk," or sour cream added to it. Reheat before serving.

Creamed Spinach and Mushrooms

2 lb. spinach	Nutmeg
Salt and pepper	Toast snippets
¼ lb. mushrooms	1 hard-boiled egg (if available)
1 oz. margarine	
½ pint white sauce	

Wash the spinach carefully, strip off any coarse stalks, and put the spinach in a pan with only the water that adheres to the leaves. Heat gently, turning occasionally, then bring to the boil. Boil for about 15 minutes, then drain thoroughly, mash finely, and season. Skin and chop the mushrooms and sauté them in the fat. When cooked add them to the white sauce, with a little grated nutmeg and salt and pepper. Make a border of the cooked spinach and pour the mushroom sauce in the middle. Garnish with toast snippets, and if possible with sieved hard-boiled egg.

Stuffed Tomatoes

4 even-sized tomatoes
1 oz. chopped ham
1 teaspoonful chopped onion
½ oz. butter
2 tablespoonfuls fresh breadcrumbs
½ teaspoonful chopped parsley
1 pinch pepper
½ cucumber
Croûtons of fried bread
Sprigs of parsley

Wash and dry the tomatoes. Cut a small round from each tomato at the end opposite the stalk, leaving it attached at one side. Scoop out the centre with a teaspoon handle. Sauté the ham and onion in the butter for about 3 minutes. Add the crumbs, parsley, seasonings, and pulp removed from the tomatoes. Fill the tomatoes with this mixture and pile neatly on top. Place the lids over and bake in a moderately hot oven (400° F.) for about 15 minutes. The cucumber garnish can be cooked in the same dish. Wipe the piece of cucumber and cut down in four strips. Wrap these in a buttered paper and bake for 15 minutes. Place the tomatoes on the croûtons of fried bread and garnish with parsley and the cucumber.

Green Salad

½ lb. raw peas
1 teaspoonful chopped chives
1 teaspoonful chopped parsley
1 teaspoonful chopped mint
Mayonnaise
1 lettuce
1 bunch watercress

Mix the peas, chives, mint, and parsley with the mayonnaise. Arrange in a dish with lettuce leaves round the edge and garnish with sprigs of watercress.

Summer Salad Bowl

2 lettuces
1 cupful green peas
1 cupful cooked potatoes
2–3 tomatoes
A few spring onions
1 teaspoonful chopped garden herbs (chervil, parsley, tarragon)
French dressing

Wash the lettuces carefully, reserving the best leaves for garnishing. Break up the remainder and combine with the peas, diced potatoes, sliced tomatoes, and thinly sliced spring onions. Add the chopped herbs to the French dressing and toss the salad ingredients lightly in it. Line the salad bowl with lettuce-leaves and pile the salad in the centre.

Russian Salad

Cooked mixed vegetables, such as carrots, peas, beans, potatoes, asparagus, turnips, etc.
A few capers, nasturtium seeds, or pickled cucumber
2–3 tablespoonfuls mayonnaise
Freshly chopped parsley
Watercress
Aspic jelly, if available

Cut the vegetables into small dice or rounds and chop the capers, nasturtium seeds, or cucumber. Mix all the ingredients with mayonnaise and serve in small individual dishes or in a large bowl, garnished with freshly chopped parsley and sprigs of watercress. If some aspic jelly is available, cut it into fancy shapes, or chop and use for garnishing.

Stuffed Tomato Salad

6 even-sized tomatoes
Cooked peas
Diced cooked carrot
Diced cooked potato
Spring onions
Salad cream
Chopped parsley
Lettuce

Cut the top off each tomato and scoop out the inside. Mix the cooked peas, carrot, potato, and finely chopped spring onion, and add sufficient salad cream to make the mixture bind together well. Fill the tomato cases with this vegetable salad, and sprinkle a little chopped parsley over the top of each. Place the tomatoes on a glass dish with some small pieces of lettuce. This salad makes a colourful accompaniment to cold meat or sliced meat loaf. If preferred, a potato-salad mixture instead of the mixed vegetables may be used to fill the tomatoes.

Orange and Watercress Salad

2–3 oranges
1 tablespoonful salad oil
1 dessertspoonful vinegar
1 teaspoonful lemon juice
Watercress
Small cress

Peel the oranges and remove all the white pith; cut them crossways into slices and remove any pips. Mix the salad oil, vinegar, and lemon juice, pour over the oranges, and allow them to stand for a short time before serving. Garnish with watercress and small cress. This salad makes a good accompaniment for hot or cold game dishes; grapefruit may be substituted for the orange, if preferred.

SAUCES AND STUFFING

Sauces are used to flavour, coat, or accompany various dishes, and are in some cases mixed in with the ingredients to bind them together. The foundation of most sauces in which flour is the thickening agent is the "roux" formed by cooking butter and flour together. The butter is melted and the flour added, and the two stirred together. The liquid is added slowly with constant stirring. The sauce must be stirred and boiled for at least five minutes to ensure thorough cooking of the starch grains. For a brown sauce dripping can be cooked until it is a golden brown. Milk, milk and water, or white stock are used for white sauces; vegetable or bone stock for brown sauces, and fish stock for fish sauces. Careful cooking and constant stirring are essential for a good sauce, and if an exceptionally glossy finish is required, the sauce should be strained through a tammy cloth, which is made from a special woollen material of fine texture. Flavouring or colouring should be added just before serving.

SAVOURY SAUCES

Basic White Sauce

1 oz. butter or margarine
1 oz. flour
½ pint milk, or milk and stock
Salt and pepper

Melt the butter, stir in the flour, then add the liquid gradually, stirring well during the process. Continue to stir until the liquid comes to the boil, then boil slowly for 3–5 minutes. Add seasonings.

Note: For a coating sauce, use only ½ pint milk or stock.

Sauces Made from the Basic Recipe

Parsley Sauce.—Add 2 tablespoonfuls freshly chopped parsley and a dash of vinegar just before serving.

Anchovy Sauce.—Add anchovy essence to taste (1–2 teaspoonfuls), omitting salt when seasoning. Add also a drop of pink colouring.

Cheese Sauce.—Add 2 oz. finely grated cheese, and season with mustard and a few drops of vinegar or piquant sauce.

Caper Sauce.—Add 1 dessertspoonful of chopped capers or pickled nasturtium seeds and 1 teaspoonful vinegar.

Mushroom Sauce.—Add 1 oz. of chopped mushrooms to the sauce and cook for 2–3 minutes before serving. If preferred, the sliced mushrooms can be sautéed in the fat when the sauce is being made.

Egg Sauce.—To ½ pint white sauce add 1–2 hard-boiled eggs, finely chopped.

Onion Sauce.—To ½ pint white sauce (made if possible partly from the vegetable liquor) add 1–2 chopped cooked onions.

Bechamel Sauce

1 pint milk
1 shallot
Piece of carrot
1 stalk of celery
1 clove of garlic
1 bay leaf
8 peppercorns
2 oz. flour
2 oz. butter
½ pint cream, if liked
Salt and pepper

Put the milk, vegetables, garlic, bay leaf, and peppercorns into a pan and bring slowly to the boil. Cover and stand near the fire for a few minutes to infuse. Strain and make a sauce, using the flour and butter in the usual way. When cooked allow to cool slightly, then add the cream and seasoning, reheat, but do not boil.

Brown Sauce

1 small onion
1 small carrot
1 oz. butter or dripping
½ pint brown stock or water
1 oz. flour
Seasoning
Gravy browning, meat cube, or glaze, if liked

Chop the onion and carrot into small pieces, melt the butter, and fry the vegetables until deep brown

in colour, but do not allow them to burn. Stir in the flour, blend with the vegetables, and continue to cook until the flour is also golden brown. Gradually add the stock, bring to the boil, stirring meanwhile, and simmer gently for 15–20 minutes, and then strain. Season to taste. If the sauce is not deep enough in colour a few drops of gravy browning may be added, or a meat cube or glaze may be used to improve the flavour.

Espagnole Sauce

2 oz. butter or dripping	1 pint brown stock
2 oz. bacon	1 dessertspoonful mushroom ketchup
1 shallot	A bouquet garni
1 large tomato	Pepper and salt
1 small carrot	
2 oz. flour	

Melt the butter and fry the chopped bacon in it, then fry the sliced vegetables until lightly browned. Add the flour and fry all to a rich golden brown. Add the rest of the ingredients and simmer for 40 minutes, then skim and strain. Reheat the sauce and season it.

Note: A tablespoonful or so of sherry may be added to the sauce just before serving.

Curry Sauce

½ oz. cooking-fat	½ pint stock
1 tablespoonful chopped onion	Salt
1 tablespoonful chopped apple	Lemon juice
1 teaspoonful curry powder	1 dessertspoonful chutney
½ oz. flour	1 teaspoonful table sauce
	1 tablespoonful sultanas

Melt the fat and fry the onion lightly, then the apple, and finally the curry powder and flour. Add the stock gradually and season with salt, boil and skim, then add the lemon juice, chutney, table sauce, and sultanas. Put on the lid and simmer for about 1 hour, stirring frequently. Strain if required.

Mustard Sauce

1 oz. margarine	½ pint water
½ oz. flour	2 tablespoonfuls vinegar
½ teaspoonful dry mustard	Pepper and salt

Melt the fat and fry the flour and mustard lightly. Add the water gradually, and then the vinegar and seasoning. Stir and boil gently for 3–5 minutes.

Hollandaise Sauce

2 tablespoonfuls water or stock	2 oz. margarine
1 dessertspoonful tarragon vinegar	Salt and pepper
2 egg yolks	1 dessertspoonful lemon juice

Put the water or stock, vinegar, and yolks of eggs into a basin and stand the basin in a saucepan of hot water. Whisk over heat until the sauce thickens, then draw the saucepan to one side and add the fat in small pieces, stirring well. Season to taste, and add the lemon juice. The sauce must not boil, or it will curdle.

Mock Tartare Sauce

Small pieces of carrot, turnip, onion, and celery	1 oz. margarine
A blade of mace	1 oz. flour
2 cloves	1 egg
1 bay leaf	½ a lemon
6 peppercorns	1 teaspoonful chopped parsley
½ pint milk or milk and water	½ tablespoonful chopped pickles
	Salt and pepper

Allow the vegetables and herbs to infuse slowly in the liquid for 20–30 minutes, then strain. Melt the margarine, stir in the flour, and fry for a minute or two without browning. Beat in the flavoured milk, adding it a little at a time to prevent lumps forming, then bring to the boil, stirring well. Allow to cool slightly, then beat in the egg and cook for a further few minutes. Add the lemon juice, the chopped parsley, chopped pickles, and seasoning to taste.

Robert Sauce

2 oz. butter	A few peppercorns
2 onions	Salt and pepper
1 tablespoonful flour	Mustard
½ pint brown stock	Vinegar
Bunch of herbs	Lemon juice
Bay leaf	

Melt the butter and fry the sliced onions in it over gentle heat until golden brown—about 10 minutes. Stir in the flour, to form a roux, then gradually add the stock and bring to the boil, stirring. Add the herbs, bay leaf, and peppercorns tied in muslin and season with salt. Cover and simmer for about ½ hour, then remove the bag of herbs and stir in the mustard, vinegar, and lemon juice to taste, with more salt and pepper if necessary. Serve with goose, pork, veal, or steaks.

Tomato Sauce

1 small onion	½ pint stock
A piece of carrot	1 oz. flour
½ lb. tomatoes	Seasoning
1 bay leaf	½ oz. dripping or margarine
A little milk	
A bunch of herbs	

Prepare the vegetables, and cut into small pieces. Place with the tomatoes and the fat in a strong pan and heat gently, stirring, until the fat is absorbed. Add the herbs and the stock and simmer for about ½ hour, then rub through a fine sieve. Add the flour blended to a smooth cream with a little milk, season and cook the sauce for a further 2–3 minutes, stirring.

Apple Sauce

2 lb. apples
1–2 oz. butter or margarine
Sugar, if required
Lemon juice, if required.

Choose good cooking apples, peel and slice with a stainless-steel knife, then cook gently to a pulp in a covered pan. Beat with a wooden spoon until smooth, and add the butter. Sugar may be added if liked, but a tart apple sauce is just the right accompaniment to a goose or duck. On the other hand, if the apples are sweet, a little lemon juice may be added.

Bread Sauce

½ pint milk or milk and vegetable stock mixed	A small blade of mace
1 teaspoonful chopped onion	2 oz. breadcrumbs (or stale bread soaked and squeezed)
1 clove	Salt and pepper
	A knob of margarine

Put the liquid into a pan with the onion, clove, and mace, and allow to infuse for about ½ hour. Strain and add the breadcrumbs, seasoning, and the knob of margarine. Leave in a very warm place at the side of the stove for 15 minutes, and make very hot before serving.

Horseradish Cream

1–2 tablespoonfuls grated horseradish	Cream or evaporated milk
1 tablespoon vinegar	Salt, pepper, and sugar

Soak the grated horseradish in the vinegar for 10–15 minutes. Stir in enough cream or evaporated milk to give the desired consistency, and season with salt, pepper, and sugar.

Maître D'Hôtel Butter

1 oz. butter	1 teaspoonful lemon juice
1 teaspoonful finely chopped parsley	Salt and pepper

Mix all the ingredients thoroughly into a creamy paste, using a fork or wooden spoon. Shape into pats and make very cold. Serve with grills, etc.

Mint Sauce

2 tablespoonfuls chopped mint	1 tablespoonful boiling water
1 teaspoonful sugar	1½ tablespoonfuls vinegar

Strip the mint from the stalks and chop it finely. Put the sugar and boiling water in a sauce-boat and stir until dissolved. Add the mint and stir in vinegar to taste.

Cranberry Sauce

Pick and wash 1 lb. cranberries and put them into a stewpan with 1 teacupful of water. Stew until reduced to a pulp, bruising them well with the back of a wooden spoon. Then add ½ lb. sugar, and a little port wine, if desired.

SWEET SAUCES

Basic White Sweet Sauce

½–1 oz. margarine	1 teaspoonful sugar
½–1 oz. flour	Vanilla essence or other flavouring
½ pint milk	

Melt the margarine, stir in the flour to form a roux, and cook for 1–2 minutes without browning. Add the milk a little at a time, stirring well to keep the mixture smooth. Bring to the boil, stirring all the time, and cook for 2–3 minutes, beating the sauce to make it smooth and glossy. Sweeten and flavour to taste and use as required.

Sweet Sauces Made from the Basic Recipe

Chocolate Sauce.—Add 1 tablespoonful of cocoa and a few drops of vanilla essence. Sweetened chocolate powder may be used in place of cocoa, in which case sugar will not be needed.

Lemon Sauce.—To the cooked sauce add lemon juice or substitute and a drop or so of lemon essence. A little extra sugar may be needed in this sauce.

Orange Sauce.—Use finely grated orange rind to flavour the sauce.

Butterscotch Sauce

3–4 oz. granulated sugar	½ oz. margarine
½ pint boiling water	2 teaspoonfuls flour
	½ pint milk

Put the sugar into a thick saucepan and heat gently until it caramelises; shake the pan during cooking to prevent uneven browning, but do not stir. When quite liquid and of a good brown colour, remove from the heat, cool slightly, and add the boiling water by degrees. Return to the heat and simmer until caramel is dissolved. Make a white sauce with the other ingredients and stir in the dissolved caramel. Boil for a further 2 minutes and serve hot or cold.

Custard Sauce

2 teaspoonfuls flour	1 teaspoonful sugar
½ pint milk	Vanilla essence
1 egg	

Blend the flour to a smooth cream with a little milk. Heat the remainder, and when hot add to the blended flour, stirring. Cool slightly, then add the egg and heat gently to cook the egg without curdling. Add sugar and vanilla essence to taste. If the sauce is to be served cold, cover while cooling to prevent skin from forming, and heat occasionally.

Chocolate Sauce

1½ oz. unsweetened chocolate	Pinch of salt
½ pint water	½ oz. butter
1 teaspoonful cornflour	2 oz. sugar
	Vanilla essence

Break up the chocolate, add half of the water, and dissolve over gentle heat. Mix the cornflour and salt to a smooth cream with a little of the remaining cold water, heat the rest and, when it is boiling, pour it on to the blended cornflour, stirring. Return it to the pan and bring to the boil, stirring. Add the dissolved chocolate, butter, and sugar, and cook for 4–5 minutes, stirring well. Lastly, add a few drops of vanilla essence.

Jam Sauce

½ teaspoonful cornflour or arrowroot	2 tablespoonfuls jam
½ pint water	A little lemon juice
	Colouring, if necessary

Blend the cornflour or arrowroot with a little water. Add the rest of the water, bring to the boil, and allow to cook for about 2 minutes. Stir in the jam, and add the lemon juice, and tint, if necessary, with a little colouring. Strain before serving.

Syrup Sauce

4 tablespoonfuls water	2 tablespoonfuls golden syrup
Juice of half lemon	

Mix all the ingredients together and boil rapidly for a few minutes.

Marshmallow Sauce

4 oz. granulated sugar	Few drops of vanilla essence
3 tablespoonfuls water	Colouring
8 marshmallows	
1 egg white	

Dissolve the sugar in the water, then boil together for about 15 minutes. Add the marshmallows, cut into small pieces with scissors. Beat the egg white very stiffly, then gradually fold in the marshmallow mixture. Add vanilla and enough carmine or cochineal to tint pale pink. Serve with ice-cream.

Note: Peppermint may be used instead of vanilla to flavour; in this case colour the sauce pale green.

Melba Sauce

4 tablespoonfuls redcurrant jelly	2 teaspoonfuls arrowroot or cornflour
3 oz. sugar	1 tablespoonful cold water
½ pint raspberry purée	

Mix together the jelly and sugar and the raspberry purée, and heat until boiling. Blend the arrowroot or cornflour with the cold water and add to the raspberry mixture. Continue cooking until the mixture becomes thick and clear, stirring all the time with a wooden spoon. Strain and cool.

Note: This is excellent to serve with peach melba and other sundæs.

Brandy Butter or Hard Sauce

2 oz. butter	1 dessertspoonful brandy
2 oz. castor sugar	

Beat the butter and sugar to a white cream, then gradually beat in the brandy. Leave in a cool place until required; serve piled up in a fancy dish.

STUFFINGS

Sage-and-onion Stuffing

2 large onions	4–5 sage leaves or 2 teaspoonfuls dried sage
Boiling water	½ teaspoonful salt
½–1 oz. butter	¼ teaspoonful pepper
4 oz. breadcrumbs	

Put the prepared onions into cold water, bring to the boil and cook for 5 minutes, then strain off the water, cover with fresh boiling water, and cook until tender. Drain well and chop finely, then add the butter, crumbs, chopped sage, and seasoning, and mix well together. Use for stuffing goose and duck, or to serve with pork.

Sausage Stuffing

1 large onion	½ teaspoonful mixed herbs
1 lb. pork sausage meat	4 tablespoonfuls fresh breadcrumbs
1 oz. dripping	Seasoning
1 teaspoonful chopped parsley	

Mix the chopped onion and the sausage meat, and sauté them in the dripping for a few minutes. Mix in the other ingredients and use as required.

Chestnut Stuffing

1 lb. chestnuts	A little grated lemon rind
½ pint stock or milk	Salt and pepper
2 oz. ham or bacon	1 teaspoonful chopped parsley
1 teaspoonful sugar	1 egg
1 oz. margarine	

Make a slit in both ends of the nuts and boil in water for 10 minutes, then skin them. Put them into a pan with stock or milk to cover, and simmer gently until tender and mash or sieve them. Pound with the finely chopped ham or bacon, add the crumbs, parlsey, melted fat, lemon rind, season with salt and pepper, add sugar, and bind with the beaten egg. Use to stuff turkey, chicken, etc.

Veal Forcemeat

2 oz. suet	¼ teaspoonful mixed herbs
1–2 oz. ham or bacon	Rind of ½ lemon
4 oz. breadcrumbs	Salt and pepper
2 teaspoonfuls parsley	Beaten egg

Chop the suet and the ham or bacon finely and mix with the crumbs; and chopped parsley, herbs, and grated lemon rind. Season, and add enough beaten egg to bind. Use for stuffing veal, chicken, rabbit, hearts, etc., or as forcemeat balls.

Oyster Stuffing

18 sauce oysters	A pinch of mace
6 oz. breadcrumbs	Salt and Cayenne
1 dessertspoonful parsley	2 oz. suet *or* 1½ oz. butter
Grated ½ lemon rind	1 egg

Beard and cut up the oysters, simmer the beards in the oyster liquor to extract the flavour, then strain. Mix dry ingredients and fat, add the oysters, the lightly beaten egg, and oyster liquor to moisten. Use for stuffing the breast of a boiled turkey. Small tinned oysters may be used for this stuffing.

Fish Forcemeat

3 oz. breadcrumbs	2 teaspoonfuls chopped parsley
1 oz. chopped suet or melted margarine	Salt and pepper
Grated rind of ½ lemon	Egg or milk
½ teaspoonful dried herbs	

Mix all the ingredients together, adding sufficient beaten egg or milk to bind.

PASTRIES

A few basic rules should be followed for successful pastry making. Working conditions must be cool, and a hot oven is essential. Handle the pastry as little as possible, and measure the ingredients accurately. Avoid stretching the pastry during the rolling. The richer puff and flaky pastries are improved if left in a cool place between rollings, and again before baking. The richer the pastry, the hotter the oven must be.

Suet Crust

8 oz. flour
1 teaspoonful baking-powder
½ teaspoonful salt
3–4 oz. chopped or prepared suet
Cold water to mix

Mix flour, baking-powder, salt, and suet together, add cold water to give a light elastic consistency, and handle as little as possible. Turn on to a floured board, knead very lightly, and use as required.

Dumplings

Roll the dough of suet-crust pastry into balls and add to boiling soups, stews, etc., allowing 20–25 minutes, according to size.

Syrup Layer Pudding

8 oz. suet crust	1 oz. breadcrumbs
1 lemon	4–6 oz. golden syrup

Make the pastry, adding the grated lemon rind to the flour. Mix the breadcrumbs and lemon juice with the syrup. Divide the pastry into six pieces, graduating in size. Put 1 tablespoonful of the syrup mixture into the bottom of a greased basin. Roll the smallest piece of pastry into a round and place on top of the syrup. Cover with a tablespoonful of syrup and then the next largest piece of pastry, rolled to a round, repeating till the pastry is used up and the basin two-thirds full. Cover with greased paper and steam 2½–3 hours. Turn out on to a hot dish and serve at once. Black treacle may be used in place of syrup, or a mixture of both.

Short-crust Pastry

8 oz. flour	4 oz. fat
A pinch of salt	Cold water

Sieve the flour and salt into a basin. Add the fat, cover it with flour, and then rub the two together with the tops of the fingers until the mixture resembles breadcrumbs. Lift up the flour and fat in the hands while doing this and let the cold air mix with them. Then make a hollow in the centre, and add cold water very gradually with the left hand while continuing to mix with the right. Add just sufficient water to make a stiff dough; if the pastry is made too moist, it will not be short. Turn the pastry on to a floured board and knead it lightly with the hand until it is free from cracks; then roll it out to the thickness required.

Cornish Pasties

6 oz. raw potato	Salt and pepper
¾ lb. lean raw steak or mutton	2–3 tablespoonfuls cold water
1 tablespoonful chopped onion	1 lb. short-crust pastry
	Yolk of egg or milk

Wash and peel the potatoes and cut into dice. Mix with the meat (cut up very small or minced), the finely chopped or minced onion, seasoning, and water. Roll out the pastry thinly and cut into rounds about the size of a saucer. Wet the edges of the pastry and put a tablespoonful of the meat mixture on each round. Fold over, press the edges of the pastry well together, and flute with the fingers. Stand the pasties upright on a baking-sheet, brush over with a little beaten egg or milk and bake in a hot oven (425° F.) till the pastry begins to brown, then reduce to a moderate heat (350° F.) and continue cooking until the meat is tender—about 1 hour in all.

Apple Pie

1½ lb. apples	½ lb. short-crust pastry
2 oz. sugar	Milk or egg white to glaze
Cold water	

Peel, core, and slice the apples. Half-fill a dish with fruit, then add sugar, the rest of the fruit, and water to cover the bottom of the dish. Roll out the pastry 3 in. wider and longer than the pie-dish. Cut off strips 1 in. wide, moisten the edge of the dish with water, and lay the pastry strips on the edge of the dish; press in place. Moisten the pastry strip with water. Lift the piece of pastry on the rolling-pin and lay it over the pie-dish, taking care not to stretch it. Press the edges in place and trim them with a sharp knife. Decorate the edges of the pie and brush over with milk or white of egg. Bake near the top of a hot oven (425–450° F.) for 20 minutes, then remove to a lower part of the oven and continue cooking until the fruit is cooked.

Bakewell Tart

4 oz. short-crust pastry	1 egg
Raspberry jam	2 oz. ground almonds
2 oz. butter or margarine	1–2 drops almond essence
2 oz. sugar	Icing sugar

Line a flan ring or sandwich tin with the pastry and spread with a layer of raspberry jam. Beat the fat and sugar together until soft and creamy. Add the beaten egg by degrees, beating very thoroughly. Stir in the ground almonds and a drop or two of almond essence and spread over the jam in the pastry case. Bake in a moderately hot oven (400° F.) for 30–40 minutes, until the tart is well risen and brown and the filling is set. Dredge with icing sugar.

Custard Tart

4 oz. short-crust pastry	½ pint milk (short measure)
1 egg	Nutmeg
½ oz. sugar	

Line a fireproof baking-plate with the pastry. Beat the egg and sugar together and pour on the hot milk, stirring meanwhile. Strain into the prepared pastry case and grate a little nutmeg over the mixture. Bake in a hot oven (425° F.) for about 10 minutes, until the pastry is set, and then reduce the heat and continue to bake in a moderate oven (375° F.) until the custard is set.

Lemon Meringue Pie

4 oz. short-crust pastry	1½ oz. sugar
1 level tablespoonful cornflour	1 lemon or 2 tablespoonfuls lemon squash
4 tablespoonfuls cold water	1 egg

Line a flan-ring or pie-plate with the pastry and decorate. Prick the bottom and bake "blind."

Meanwhile, blend the cornflour with the water, add the sugar, lemon juice or squash, and grated lemon rind. Bring to the boil in a small saucepan, stirring well, and boil for 2 minutes. Allow to cool slightly, then stir in the egg-yolk and pour into the pastry case. Whip the white of egg very stiffly, fold in a little sugar, and pile on top. Bake in a moderate oven (375° F.) for a few minutes, until a light golden-brown.

Syrup Tart

6 oz. short-crust pastry	2 oz. breadcrumbs
3–4 tablespoonfuls golden syrup	Juice of ½ a lemon

Line a sandwich tin or a fireproof plate with the pastry, prick the bottom and place breadcrusts on it to prevent the pastry rising. Bake in a hot oven (450° F.) for about 15 minutes. Remove from the oven, pour in half the syrup, sprinkle on the breadcrumbs, add the lemon juice and the rest of the syrup. Decorate with strips of pastry and bake in a moderately hot oven (400° F.) for 20 minutes.

Flaky Pastry

8 oz. flour	A good squeeze of lemon juice
¼ teaspoonful salt	Cold water to mix
3 oz. lard	
3 oz. butter or margarine	

Sieve the flour and salt into a basin. Divide the fat into four portions, using half-lard and half-butter in each portion. Rub one portion of fat into the flour until it is as fine as breadcrumbs and mix to a soft dough, using lemon juice and water. Knead lightly and roll out into a long strip. Put one-third of the remaining fat in small flakes over two-thirds of the pastry, taking care not to put it too close to the edges. Fold the pastry in three, the plain part being folded over the fat. Seal the edges of the pastry with a rolling-pin and half-turn it to bring the folded edges to the sides. Press firmly and again roll out into a long strip. Repeat this process twice, using up the remaining two-thirds of fat. Roll out and fold once more, and allow the pastry to stand in a cool place until required.

Sausage Rolls

Roll some flaky (or rough puff) pastry rather thinly and cut this into strips about 3½ by 5 in. Divide a raw sausage into four or six pieces and roll the pieces to the required shape. Place a piece of sausage across one end of each strip of pastry, damp the edges, fold the rest of the pastry over, seal the edges neatly, and glaze if required. Bake in a hot oven (450° F.) for 20–30 minutes.

If larger rolls are needed, the sausages may be semi-cooked (prick and bake), left till cold, and then placed whole on the pastry. Brush the tops with beaten egg and bake as above.

Prawn Patties

8 oz. flaky pastry	¼–½ pint white sauce
Egg to glaze	Parsley
½ pint picked prawns	Watercress

Roll out the pastry to ¼ in. in thickness and cut it out with a fluted pastry cutter. Using a smaller cutter, mark the centre of each round, cutting about half-way through the pastry. Glaze the top with a little beaten egg and bake in a hot oven (450–475° F.) for 15–20 minutes, until well risen and golden-brown. Carefully take out the round "lids." Mix the prawns with enough well-flavoured white sauce to bind them together, and fill the patties with this mixture. Replace the "lids" if desired. Garnish the patties with parsley and watercress, and serve them either hot or cold, with a few large prawns arranged to decorate the dish.

Eccles Cakes

8 oz. flaky (or rough puff) pastry	1 oz. chopped candied peel
4 oz. cleaned currants	1 oz. sugar
Nutmeg and spice to taste	1 oz. butter
	White of egg to glaze
	Sugar to dredge

Roll the paste to ⅛ in. thick and cut into rounds about 4″ in diameter. Mix the other ingredients and place a spoonful in the centre of each round. Damp the edges and draw them together, forming a ball-like shape. Turn the smooth side uppermost, flatten into a round, and cut lightly, marking the top into squares, so that the currants show. Brush with white of egg, sprinkle with sugar, and bake in a hot oven (450° F.) for about 20 minutes.

Mince Pies

12 oz. flaky pastry	Beaten egg
Mincemeat	Icing sugar

Divide the pastry in half and roll it out thinly. Cut rounds of pastry large enough to fit some patty tins and put about 2 teaspoonfuls of mincemeat in each. Roll out the rest of the pastry and cut out slightly smaller rounds for the lids. Damp the edges of the pastry lining the patty tins and press on the tops. Flake up the edges with a knife, and snip the top of each, using scissors. Brush the top of each mince pie with beaten egg, and bake in a hot oven (450–475° F.) for 25–30 minutes. Dredge the tops with icing sugar, and serve the pies hot or cold, as preferred. Short-crust, rough puff, or puff pastry may also be used, and fruits, such as sliced apples or raspberries, make a variation in filling.

Rough Puff Pastry

8 oz. flour	2–3 oz. lard
¼ teaspoonful salt	¼ teaspoonful lemon juice
2–3 oz. butter or margarine	Cold water

Sieve the dry ingredients into a basin, and add the fats, cut into pieces the size of a small nut. Add the lemon juice, mix into a dough with cold water, and turn on to a floured board. Roll out into a long, narrow strip, always rolling with a forward movement and not too heavily. Fold in three, turn the pastry half-round, bring the join to the right-hand side, seal the edges, and roll again. Repeat this until the pastry has had four turns. (A roll and a fold is called "a turn.") Cool the pastry thoroughly before using; if wrapped in a floured cloth or greased paper it can be kept overnight.

This pastry is useful for meat pies and savoury pastries of all kinds.

Puff Pastry

8 oz. butter	A squeeze of lemon juice
8 oz. flour	Cold water
Salt	

This pastry, when well made, consists of innumerable thin layers which melt in the mouth, and in both appearance and taste it is superior to any other type. Its characteristic lightness depends on the amount of cold air enclosed by the special method of making, and the expansion of that air during the baking.

Butter gives the best results, but a mixture of two-thirds margarine and one-third lard may be used. If butter is used, it should first be washed to remove all salt and butter-milk. Put it into a basin under a tap of cold running water, heat the hands in hot water and chill them in cold, then squeeze the butter in the water until of a waxy consistency and easy to handle. Then dry it in a lightly floured cloth and pat it until every drop of water has been expelled.

Sieve the flour into a basin, add a pinch of salt, then take a piece of the butter about the size of a walnut and rub it into the flour with the finger-tips. Make a well in the centre, put in a squeeze of lemon juice, which helps to lighten the pastry, and add sufficient cold water to form a dough. The aim should be to get both the dough and the butter of the same consistency.

Form the dough into one lump and turn it out on a lightly floured board. Knead vigorously for about 10 minutes, until it is smooth and velvety and no longer sticks to the fingers. When it is smooth and elastic, take the rolling-pin and roll it out into a thin square or round. Shape the remainder of the butter into a flat cake and place it in the centre. Fold over the sides of the dough so as to enclose the butter completely, at the same time leaving room for the spread of the butter when rolling. Pat down with the rolling-pin and roll out into a long narrow strip. Now fold the pastry in three, folding the first flap from you and the second towards you. Then turn the

pastry half-way round, bringing the folds to the right-hand side.

Press the edges firmly with the rolling-pin, to enclose all the air possible; this finishes what is called one "turn" in pastry-making. Puff pastry requires seven "turns" or rollings in all, but as too much rolling at one time would make it too soft, it has now to be put aside in a cool place for at least ¼ hour, covered with greaseproof paper or with muslin wrung out in cold water. Bring it out again on to the board and give it two turns in exactly the same way as the first one. Again lay it aside, and repeat this twice more, until the pastry has had its seven turns in all.

The baking of puff pastry requires as much care and judgment as the making. The secret of success lies in having the pastry cold and the oven hot. The temperature should be from 450° to 500° F. to begin with, and when the pastry has risen its full height, the heat may be reduced slightly to allow it to finish cooking.

Puff pastry is used for any dish requiring a very light pastry, such as *vol-au-vent* patties, small French pastries, mince pies, etc.

Chicken Vol-au-vent

8 oz. puff pastry	½ pint white coating sauce
Beaten egg	2 oz. mushrooms
6 oz. diced cooked chicken	Cress and parsley

Roll out the pastry to about 1 in. in thickness and cut into a round, using a large cutter or a saucer. Using a smaller cutter or a knife, mark another circle inside, to form a lid. Make some decorative cuts around the top edge of the pastry and brush it with a little egg. Bake in a hot oven (475° F.) for 30–35 minutes, covering the top of the pastry if it tends to become too brown. When it is cooked, remove the lid and take out any soft dough inside. Heat the diced chicken in the white sauce and fill the vol-au-vent case. Serve garnished with grilled mushrooms, and with cress and parsley.

Jam Puffs

Puff pastry	Egg white
Jam	Castor sugar

Roll the pastry thinly and cut it into squares. Put a little jam on one side, fold the pastry over to form a triangle and seal the edges firmly. Brush over with egg white and sprinkle with sugar. Bake in a hot oven (475° F.) for 10–15 minutes.

Vanilla Slices

6 oz. puff (or flaky) pastry	Vanilla essence
Mock cream, cream, or thick custard	Raspberry or strawberry jam
	White glacé icing

Roll the pastry ¼ in. thick and form into a strip 4 in. wide. Cut into oblong pieces about 1½ in. wide and bake in a hot oven (475° F.) for 10 minutes. Allow the slices to become quite cold, then sandwich two or three of them together with jam and the mock cream, cream, or thick custard, which has been flavoured with vanilla essence. Top the slices with a little white glacé icing, made according to directions. Serve these pastries as a cold dessert, or for tea.

Choux Pastry

¼ pint water	2½ oz. flour
1 oz. butter or margarine	A pinch of salt
	2 eggs

Place the water and fat in a saucepan and bring to the boil. Add the flour and salt to the mixture and beat well over a low heat until it forms a ball. Cool slightly and add the eggs a little at a time, beating well. Using a forcing-bag, force into éclair shapes on to a greased tin. Bake in a moderately hot oven (400° F.) for about 30–40 minutes. Allow to cool slightly, slit down one side, and remove any soft part from the inside. Fill with sweet or savoury filling.

Chocolate Eclairs

Synthetic or fresh cream or thick custard	Choux pastry
	Chocolate glacé icing

Make the choux paste, and put into a large forcing bag fitted with a plain ½- or ¾-in. nozzle. Pipe fingers of paste about 3½–4 in. long on to a greased baking sheet, keeping the éclairs very even in size. Bake in a moderately hot oven (400° F.) for about 30–40 minutes, according to size, until the éclairs are well risen, golden-brown, and very light in texture. Remove them from the tin, slit each down the side to allow the steam to escape, and put on a rack to cool. Fill them with whipped cream, mock cream, or a thick sweet custard, and coat the top of each with a little chocolate glacé icing.

Cream Buns

Sweetened or mock cream, or thick custard	Choux pastry
	Icing sugar or chocolate sauce

Make the choux paste and put it into a forcing-bag fitted with a plain ½- or ¾-in. nozzle. Pipe the mixture in rounds on to a greased baking-tin, which should be covered with an inverted meat tin, or into a tin which has a tightly fitting lid. Cover, and bake in a moderately hot oven (400° F.) for 45–50 minutes without opening the tin, as this would cause the steam to escape and the buns to collapse. When they are cooked, remove them carefully, slit to allow the steam to escape and leave them on a rack to cool. Fill them with cream or custard and dredge with icing sugar, or serve with a chocolate sauce.

Profiteroles

To make these miniature cream buns, force small balls of choux pastry through a ½-in. plain pipe on to a baking-sheet, and bake in a moderately hot oven (400° F.) till well risen, crisp, and golden-brown (20–25 minutes). Split and cool on a rack. Fill with cream, and ice with glacé icing.

Flan Pastry

Flan or biscuit crust is a richer, sweetened type of short-crust pastry, suitable for flans and cold lunch or dinner sweets and for tea-time pastries.

Basic Recipe

4 oz. flour	1 teaspoonful sugar
A pinch of salt	1 egg yolk
2 oz. fat	Cold water to mix

Sieve the flour and salt into a bowl and rub in the fat (margarine or a mixture of margarine and white fat) using the finger-tips. Add the sugar and mix with the egg-yolk and sufficient cold water to make a stiff dough. Knead slightly till it is quite smooth, then use as required. To line a flan ring: Place a flan ring on greaseproof paper on a baking-tin. Line the flan ring with pastry, without stretching it. Lightly roll across top of flan to trim edge cleanly. Put greaseproof paper in the flan and fill it with baking-beans. (A sandwich tin may be used instead of a flan ring.)

Flans are frequently baked "blind," but the filling is sometimes added first and cooked with the pastry. Flan pastry should be cooked in a hot oven (425° F.); after about 10–15 minutes remove the beans and lower the temperature to finish cooking the pastry a further 5–10 minutes.

Mixed Fruit Flans

Bake some pastry flan cases and fill with fresh, tinned, or lightly stewed fruit, drained free of juice. Make a jelly glaze by dissolving 1 teaspoonful of gelatine (or more, according to type) in ½ pint of the sweetened fruit juice. When just beginning to set, pour it over the fruit.

Balmoral Tartlets

6 oz. flan pastry	½ oz. cake-crumbs
1 oz. margarine	1 oz. glacé cherries and candied peel, mixed
1 oz. castor sugar	¾ oz. cornflour
1 egg	

Line ten to twelve patty tins with the pastry. Cream fat and sugar until light and white, and beat in egg-yolk. Add the crumbs, shredded cherries, and peel and cornflour. Fold in the stiffly beaten egg-white. Put thin strips of pastry over the top, and bake in a moderate oven (375° F.) for 20 minutes.

Hot-water Crust Pastry

8 oz. flour	¾ gill hot water or milk and water
½ teaspoonful salt	
2 oz. lard	

Sieve the flour and salt into a warm basin. Melt the lard in a small saucepan, add the liquid,

and bring just to boiling point. Pour this mixture into the centre of the flour and mix quickly into a paste. Turn out on to a floured board and knead with the hands until smooth and free from cracks. Form into the shape required as quickly as possible, as this pastry hardens on cooling.

Raised Veal-and-ham Pie

For the Filling

12 oz. veal	Pepper and salt
¼ lb. ham	Cold water
Parsley	2 eggs
1 lemon	Some jelly stock

For the Pastry

1 lb. flour	1½ gills water or milk and water
1 teaspoonful salt	Yolk of egg to glaze
4 oz. lard	

To Prepare the Filling.—Remove any skin and bones from the meat, wipe with a damp cloth, and cut it in small pieces. Add to it the ham, cut in small pieces, and season with chopped parsley, a little grated lemon rind and juice, pepper, and salt. Mix well together and moisten with a little cold water. Hard-boil the eggs and cut them into six to eight pieces.

To Make the Pie-crust.—Make the pastry as directed above. Cut off about a quarter of the quantity and keep it warm for making the lid and decoration later on. Mould the larger piece with the hands into an oval or round pie-case, making it the desired height and with walls and bottom of an equal thickness. At first the pastry may be inclined to collapse, but as it hardens it will stand up and retain its form. Sometimes a jar or tin is put in the centre to help with the moulding.

To Finish the Pie.—Fill the case with the meat mixture and eggs, and shape it up again if necessary. Roll out the remaining piece of pastry, wet the inside edge of the pie-crust and lay on the cover. Press the two edges together, and trim round neatly with a pair of scissors, leaving a ridge about ½ in. in height standing straight up round the pie. Snip this ridge with the scissors at a distance of ½ in. apart. Then, with the fingers bend the fringe-like pieces outwards and inwards alternately, to make a pretty edge. Make a good hole in the centre of the pie and brush all over with yolk of egg beaten with a little water. Roll out any remaining scraps of pastry and cut out leaves and narrow strips for decoration. Fix these on to the sides and top of the pie and give them also a coating of egg. Pin or clip a double piece of stiff kitchen paper (greased on the inside) round the outside of the pie, to keep it in position. Lift the pie with a fish-slice or broad knife and place it on a greased baking-tin.

Bake in a hot oven (425° F.) for 15–20 minutes, and then in a cooler one for 1½ hours or longer, until the meat feels quite tender when tested with a skewer and the pastry is golden-brown. Have ready some well-seasoned stock that will jelly when cold: this may be made from the bones and trimmings of the veal, with a little gelatine added if necessary. Fill up the pie with this by means of a filler, and set it aside until cold. Serve with salad.

Pork Pie

1 lb. lean pork pieces	Pepper and salt
1 apple	1 lb. hot-water crust
A pinch of powdered cloves	Egg yolk
	Stock

Wipe the meat and cut into small pieces. Peel, core, and slice the apple and mix it with the meat, together with the cloves and seasoning. Sprinkle with 1 tablespoonful of water. Wash any bones, place them in a pan, cover with cold water, and allow to simmer gently to make stock for the pie.

Make the pastry; cut off one-quarter of the paste and leave it in a warm place. With the remainder line the raised pie mould, or shape it by hand into an oval or round case, then fill up with the prepared meat mixture. Roll the reserved piece of pastry to form a lid. Make a hole to allow the steam to escape, trim the edges, and decorate as desired. Brush the top with egg yolk, and if a mould is not being used, pin a band of greased paper round the pie. Bake in a moderately hot oven (400° F.) for about 1 hour, then reduce to a moderate heat (350° F.) and cook until the meat feels tender when tested with a skewer. When the pie is cooked fill it up with well-seasoned stock and serve hot or cold.

An economical raised pie can have sausage meat as its main filling. Add some hard-boiled egg, herbs, and a par-boiled onion, all finely chopped. Season well, and fill the pastry case. Bake in a hot oven (425° F.) for about ½ hour to cook the pastry, then reduce temperature and cook for a further hour.

Game Pie

½ lb. veal and	1 blackcock, or other game bird
½ lb. pork *or*	1 lb. hot-water crust
1 lb. sausage-meat	Beaten egg to glaze
Seasonings	Stock
1 rasher bacon	

Cut up the meat and mince it finely, mixing it with the seasonings. Cut the bacon into small pieces and the game into small joints, removing the bones. Line a tin or pie mould with pastry and put a layer of minced meat (or sausage-meat) at the bottom and round the sides. Put the game and bacon in the pie and then a layer of meat or sausage-meat. Cover with pastry and decorate. Glaze the top and bake for about 2 hours in a moderately hot oven (400° F.). Add stock.

PUDDINGS HOT AND COLD

Baked Custard (Basic Recipe)

1 pint milk	1 oz. sugar
2 eggs	Nutmeg

Heat the milk, but do not boil it. Beat the eggs and the sugar, then add the hot milk, stirring. Strain into a greased pie-dish and grate a lit[tle] nutmeg on the top. Bake in a slow oven (350° F.) for about 40 minutes, until the custard is set.

On no account allow the mixture to boil, or the eggs will curdle.

Bread-and-butter Pudding.

2–3 slices thin bread and butter	½ oz. sugar
1–2 oz. currants or sultanas	½ pint milk
	1 egg
	Nutmeg

Cut the bread and butter into neat strips, and lay in a buttered pie-dish, buttered side up, sprinkling each layer with fruit and sugar (but omitting fruit in the top layer). Heat the milk and pour on to the beaten egg. Strain into the pie-dish, grate nutmeg on top, and stand aside for ½ hour to let the bread swell. Bake in a moderate oven (375° F.) for about ½ hour, until set and lightly browned.

Queen of Puddings

½ pint milk	½ oz. sugar
¼ pint breadcrumbs	2 egg yolks
Grated rind of 1 lemon	2 tablespoonfuls raspberry or other jam
½ oz. butter	

For the Meringue

2 egg-whites	2 oz. sugar

Heat the milk and pour it on to the bread-crumbs; add the lemon rind, butter, and sugar and leave aside for about ½ hour for the bread to swell. Beat in the egg-yolk and pour the mixture into a greased pie-dish. Bake in a moderately hot oven (375° F.) for about ½ hour, until set.

Spread a thick layer of jam on the top, heating the jam if necessary, so that it will spread easily. Whisk the egg-whites very stiffly, then fold in 1½ oz. (1½ tablespoonfuls) of the sugar. Pi[le] on top of the pudding and dredge with the remaining sugar. Return to a moderate oven (350° F.) and leave for 20–30 minutes, until the meringue is lightly coloured and crisp to the touch.

Canary Pudding

4 oz. margarine	½ teaspoonful baking powder
4 oz. sugar	A pinch of salt
2 eggs	Milk, if necessary
4 oz. flour	

Cream the fat and sugar until light and fluffy. Add the eggs one at a time, beating well after each addition. Sieve the flour, baking-powder, and salt, and fold all into the creamed mixture. Ad[d]

milk, if required, to give a dropping consistency. Put the mixture into a greased basin, cover with greaseproof paper, and steam for 1½ hours. Serve with sauce.

Variations on Canary Pudding

Syrup Pudding.—Put 2 tablespoonfuls golden syrup into the greased basin before adding the pudding mixture.

Lemon or Orange.—Add the finely grated rind of 1 lemon or orange after beating in the eggs.

Chocolate.—Sieve 1 oz. cocoa into the dry ingredients, and add a little extra liquid to mix.

Ginger.—Add 2 oz. chopped preserved ginger to the dry ingredients.

Spotted Dick

8 oz. flour	4 oz. finely chopped suet
¼ teaspoonful salt	3 oz. sugar
1 teaspoonful baking-powder	4 oz. currants
	Milk to mix

Sieve the flour, salt, and baking-powder. Add the suet, sugar, and cleaned currants. Mix with sufficient milk to make a soft dough. Grease and flour a pudding-cloth, place the dough on the cloth, and tie both ends with a piece of string, leaving enough room for the pudding to swell. Cook in fast-boiling water for 2 hours.

Christmas Pudding

6 oz. flour	2–3 fresh eggs
½ teaspoonful mixed spice	A few drops of almond essence
¼ teaspoonful grated nutmeg	A few drops of vanilla essence
2 oz. breadcrumbs	1 teaspoonful lemon juice or substitute
4 oz. chopped suet	1 small teaspoonful gravy browning or caramel
1–1½ lbs. mixed dried fruit	Milk or milk and water to mix, with a little brandy if available.
Grated rind of 1 orange	
1 grated carrot *or*	
1 finely chopped apple	
3 oz. sugar	

Sieve the flour and spices into a bowl, and add the breadcrumbs, suet, cleaned and prepared dried fruit, grated orange rind, carrot or apple, and the sugar. Mix with the beaten eggs, essences, lemon juice and gravy browning, adding a little liquid to give a stiff dropping consistency.

If suet is not available, substitute 2 oz. margarine and 2 oz. cooking-fat. This should be rubbed into the flour before the rest of the ingredients are added.

Three-quarters fill one large well-greased basin (or two small ones), cover closely with greased paper or a floured cloth, and steam for 5–6 hours.

When the pudding is cooked, allow the basin and covering to dry thoroughly, then place a clean cloth or greaseproof paper over the original coverings (which will have been sterilised by being boiled with the pudding). If protected in this way the pudding will be ready for further cooking on Christmas Day. Store in a cool, dry place.

Basic Batter Recipe

4 oz. flour	1 egg
¼ teaspoonful salt	½ pint milk

Sieve the flour and salt into a basin and make a well in the centre. Drop in the egg and half of the milk, and mix in a little of the flour at a time, using a wooden spoon and keeping the mixture smooth, until a thick creamy mixture is obtained. Beat for 5–10 minutes until the mixture is full of bubbles. Stir in the rest of the milk and cover and stand, or use at once.

Coating Batter

4 oz. flour	1 egg
¼ teaspoonful salt	¼ pint milk

Sieve the flour and salt into a basin and make a well in the centre. Drop in the egg and half of the milk, and mix in a little of the flour at a time, using a wooden spoon and keeping the mixture smooth, until a thick, creamy mixture is obtained. Beat for 5–10 minutes until the mixture is full of bubbles. Stir in the rest of the milk and cover and stand, or use at once.

Pancakes

Make the batter according to the basic recipe opposite. Warm a small frying-pan, rub with a little salt and kitchen paper and wipe clean. This "tempering" ensures that the pancakes will not stick, and it need be done only at the beginning of the frying.

Melt the cooking-fat in a small pan, pour a little into the prepared frying-pan, and when smoking hot pour it back into the saucepan; a film of fat will be left, which will be sufficient for frying the pancakes.

Pour in slowly just enough batter to cover the bottom of the pan. When set and lightly browned on one side, turn or toss and cook the other side. Turn out on to a sugared paper, dust with castor sugar, sprinkle with lemon juice, and roll up.

Apple Fritters

Coating batter	Fat for frying
Cooking-apples	Sugar

Make some coating batter according to the directions. Peel and slice the apples in rings. Dip the apple rings into the coating batter, using a skewer to lift them out. Put them into smoking hot fat. Fry until golden-brown on one side, then turn them over to cook the other side. Drain thoroughly before serving. Quartered bananas and sections of orange, or halved peaches, also make good fruit fritters.

Serve fritters as soon as possible after making, as they soon lose their crispness. They may be rolled in sugar, or accompanied by a sweet sauce.

Apple Charlotte

1 lb. apples	1 lemon
3 oz. breadcrumbs	4 oz. sugar
2 oz. grated suet	2 oz. butter

Peel and slice the apples. Mix together the breadcrumbs, suet, grated lemon rind, and sugar. Put a layer of apples in a pie-dish, then a layer of the breadcrumb mixture, add a squeeze of lemon juice and a few pieces of butter Repeat until the dish is full, finishing with a layer of breadcrumbs and a little butter. Bake in a moderate oven (350° F.) about 1¼ hours or until the apples are tender. Serve with custard or cream.

An alternative method is to line the dish with the breadcrumb mixture (reserving a little for the top), fill with the sliced apples and cover with the remaining breadcrumbs, etc. Bake as above.

Fruit Jelly

¼ pint fruit-squash juice	¾–1 oz. gelatine
¾ pint hot water	Sugar to taste

Mix the fruit squash with the water. Dissolve the gelatine in ¼ pint of the mixture over a gentle heat, add to the remaining liquid and sweeten to taste. Pour into a wetted 1-pint mould and put in a cool place to set. Turn out and decorate with slices of oranges and other fresh fruit, sprinkled with sugar.

Milk Jelly

1 pint milk	2 oz. castor sugar
Thinly peeled lemon rind	¾–1 oz. gelatine
	A little water

Put the milk, lemon rind, and sugar into a pan, and allow them to infuse over gentle heat for about 10 minutes. Dissolve the gelatine in the water and add the cooled milk. Strain the mixture into a wetted mould and leave to set. Turn out the jelly, dip mould into fairly hot water (allow longer for a china one), free edge of jelly, invert on to the dish, and shake well.

Apple Snow

2 sponge cakes	Juice of ½ lemon
½ pint cup custard	1 white of egg
3 oz. sieved stewed apple	Colouring, if liked
3 oz. castor sugar	Cherries, angelica, to decorate

Cut the sponge cakes into thin slices, lay in a glass dish and pour the custard over; allow to soak. Put the apple pulp in a basin and add the sugar and lemon juice. Whisk the white of egg until stiff, add to the apple mixture, add colouring if liked and continue whisking until stiff and very fluffy. Pile on to the custard in the dish and serve at once, decorated with cherries, angelica, etc.

Honeycomb Mould

2 large eggs	½–¾ oz. powdered gelatine
1 pint milk	2 tablespoonfuls water
1½ oz. sugar	
Vanilla essence	

Separate the yolks and whites of the eggs. Make a custard with the yolks, milk, and sugar, and flavour with vanilla. Dissolve the gelatine in the water, and add it to the custard. Whisk the egg-whites very stiffly and fold lightly into the cool custard mixture. Pour into a glass dish or mould and turn out when set.

Charlotte Russe

½ pint lemon jelly	2 tablespoonfuls milk
Cherries and pistachio nuts, or angelica	½ pint cream
8–10 Savoy fingers	1 tablespoonful brandy or ½–1 teaspoonful vanilla essence
½ oz. gelatine	1½ oz. castor sugar
2 tablespoonfuls water	

Pour a thin layer of jelly into the bottom of a plain 1-pint soufflé tin and allow to set. Decorate with cherries and pistachio nuts, pour over a thin layer of jelly and allow to set. Line the sides of the mould with Savoy finger biscuits, trimming them at the sides and ends and dipping the ends in the jelly, before putting them into position. Allow to set. Pour in a thin layer of jelly. Dissolve the gelatine in the water over gentle heat and add the milk. Whip the cream until fairly stiff, stir in the gelatine, flavouring, and sugar. Put into the prepared mould and allow to set. When quite set turn out carefully on to a glass or silver dish.

Summer Pudding

2 tablespoonfuls water	4 oz. bread
4 oz. sugar	Whipped cream or custard sauce
1 lb. raspberries and red-currants	

Put the water and sugar together and bring to the boil, add the fruit and stew carefully, until tender. Line a pudding-basin with thin slices of bread, pour in the stewed fruit, and cover with thin slices of bread; the basin should be full. Place a saucer with a weight on it on top of the pudding. Leave for several hours. Turn out and serve with whipped cream or cold custard sauce.

Chocolate Soufflé

1 oz. almonds	2 tablespoonfuls water
2 oz. chocolate	Vanilla essence
½ pint milk	¼ pint cream or evaporated milk
3 eggs	Pistachio nuts
2 oz. castor sugar	Whipped cream
½ oz. gelatine	

Prepare a soufflé case. Blanch the almonds, shred them, and brown lightly in the oven. Dissolve the chocolate in the milk, whisk the egg-yolks, sugar and dissolved chocolate over a pan of very hot water until thick and creamy, then remove from the heat. Dissolve the gelatine in water then stir into the whisked mixture, together with the chopped almonds and vanilla essence. Fold in the whipped cream lightly. Whip up the whites of egg very stiffly and fold them into the mixture. Pour into the prepared soufflé case and leave to set. Before serving, decorate with pistachio nuts and whipped, sweetened, and flavoured cream.

Note: To prepare soufflé case cut a strip of firm paper long enough to go round the soufflé case, overlapping slightly and deep enough to come about 2 in. above the rim of the case. Tie firmly round the case with string.

Lemon Mousse

2 tablespoonfuls sugar	½ oz. gelatine
1 large lemon	2 tablespoonfuls water
3 eggs	Cream

Prepare a soufflé case. Add the sugar and the grated rind of ½ lemon to the egg-yolks and beat until light and creamy. Add the strained lemon juice. Dissolve the gelatine in the water over gentle heat and add it to the egg mixture. Beat until the mixture is well incorporated. Fold in the stiffly beaten whites of egg. Pour the mixture into the prepared case and leave to set. Decorate with whipped, sweetened, and flavoured cream.

Vanilla Ice
(Using gelatine)

1 teaspoonful custard powder or cornflour	A few drops of vanilla essence
½ pint milk	1 teaspoonful gelatine dissolved in 2 tablespoonfuls of water
1 egg	
1 tablespoonful sugar (approx.)	

Blend the custard powder or cornflour with a little of the milk. Bring the rest of the milk to the boil and pour on to the blended mixture, stirring well. Return to the saucepan, bring to the boil, and boil for a minute or two, stirring. Remove from the heat, add the beaten egg, and cook gently for a further minute or so, still stirring. Remove from the heat and add the sugar and vanilla essence to taste.

Dissolve the gelatine in the water over gentle heat, and when it is quite dissolved stir it into the custard mixture. Allow to cool, beating or whisking at intervals to prevent a skin forming and to aerate the mixture. Freeze in the usual way.

BREAD AND ROLLS

The processes in bread-making should be followed carefully, bearing in mind that yeast requires a warm temperature in which to live. Only sufficient yeast should be bought for immediate use, as it will only keep a day or two. Dried yeast can, however, be kept in a tin for about six months. The following processes are the basis of all yeast cookery:

Warming.—Warm the bowl of flour and liquid (water, or milk and water). The temperature of the liquid should be lukewarm or blood heat (98° F.).

Creaming the Yeast.—Add ½ teaspoonful of sugar to the yeast for creaming.

Adding the Fat.—Incorporate the fat into the flour, either by rubbing it in or by adding it in melted form.

Setting the Sponge.—Pour the mixture of yeast and water into a well in the flour, and leave to set the sponge for 10–15 minutes.

Mixing the Dough.—Mix the dough to obtain a soft elastic and almost sticky mixture, allowing about ½ pint liquid to 1 lb. flour.

Kneading.—Unless kneading is thorough, the bread will be full of holes. Turn the dough on to a floured board and knead by lifting the edge of the dough, and bringing it to the centre.

Rising.—Leave the dough in a bowl covered with a damp cloth in a warm place to rise. It should be left until it has doubled its size.

Shaping.—Knead the dough for another 3 minutes and cut into required shapes, allowing the tins to be three-parts filled.

Proving.—Put the prepared loaves or rolls in the tins and leave in a warm place for 10–20 minutes to prove.

Baking.—Put the loaves in a hot oven for about 15 minutes, to kill the yeast, and then lower the heat to finish cooking. Allow ¾–1 hour for a 2-lb. loaf. To test tap the underside of the loaf, and if a hollow sound results the bread is cooked. Leave to cool on a wire tray.

Basic Bread Recipe

3½ lb. flour	1 teaspoonful sugar
½ oz. salt	1¾ pints tepid water (approx.)
1 oz. yeast	

Follow the method shown above.

Brown Bread

10 oz. white flour	½ oz. yeast
1½ teaspoonfuls salt	¾ pint tepid water
10 oz. wholemeal	

Sieve the flour and salt into a warm bowl and add the wholemeal. Cream the yeast and add the tepid water. Strain into the flour, mix, and knead thoroughly till smooth. Set to rise for 1 hour, then knead slightly. Form into two loaves, put into warm floured tins, and set to prove for 15 minutes. Bake in a hot oven (450° F.) for about 45 minutes, until the bread feels light and is crisp outside.

Milk Rolls

1 lb. flour	About ½ pint milk and water
Salt	A little beaten egg to glaze
2 oz. lard	
½ oz. yeast	

Warm the flour, add about ½ teaspoonful of salt, and rub in the lard. Cream the yeast and add most of the liquid, then add this to the flour and mix to an elastic dough. Knead well. Put to rise for 1 hour, or until double the size. Turn on to a floured board and knead well. Shape into rolls, dinner buns, or twists. Put on to a warmed, greased tin and prove for 10–20 minutes, until they have risen well, but avoid overproving. Bake in a hot oven (450° F.) for 15–30 minutes, according to size. Glaze with beaten egg.

Chelsea Buns

8 oz. flour	¾ gill warm milk and water
A pinch of salt	1 oz. margarine or lard
3–4 oz. currants and sultanas	1 egg
2 oz. sugar	A little melted fat
½ oz. yeast	2 teaspoonfuls sugar to glaze

Sieve together the flour and salt and put to warm. Clean the currants and sultanas and mix with 2 teaspoonfuls of the sugar. Cream the yeast with ½ teaspoonful of sugar and add it to the liquid. Add this to one-third of the flour and set it to sponge. Rub the fat into the remaining flour, add the rest of the sugar, and gradually beat in the egg. Next mix in the sponged mixture. Beat all thoroughly with the hand and put in a warm place to rise. When it has doubled its size knead lightly on a floured board and then roll into an oblong strip. Brush over with melted fat and sprinkle evenly over it the mixed fruit and sugar. Roll up and cut into twelve even-sized slices. Pack lightly, cut side down, into a greased tin, which should have straight sides, (*e.g.*, A Yorkshire pudding-tin). Allow to prove for 15 minutes, then bake in a hot oven (450° F.) for 15–20 minutes. Glaze with sugar and water.

Doughnuts

8 oz. flour	Castor sugar
A pinch of salt	1 egg
2 oz. margarine	Jam
½ oz. yeast	Fat for frying
3–4 tablespoonfuls warm milk	Ground cinnamon (optional)

Warm the sieved flour and salt in a basin and rub in the margarine. Cream the yeast with 1 teaspoonful castor sugar and add to it the tepid milk and beaten egg. Pour into the centre of the flour and mix to a soft dough. Beat well with a wooden spoon or the hand, and leave to rise until the dough becomes twice the original size; then knead lightly. Divide into ten to twelve pieces. Shape each into a ball, flatten a little, and place about ¼ teaspoonful of jam in the centre of each piece. Gather the edges together over the jam, forming balls. Place on a greased and floured tin and leave in a warm place for a few minutes to prove. Heat some deep fat until smoking faintly but not too hot, and fry the doughnuts in it until golden-brown and cooked through (about 5 minutes). Drain, then turn out on to a paper and dredge with castor sugar. If preferred, sprinkle with a little ground cinnamon mixed with sugar. Serve very fresh.

Crumpets

½ oz. yeast	A pinch of bicarbonate of soda
1 pint milk and water	1 teaspoonful salt
1 lb. flour	

Cream the yeast with a little of the tepid liquid, add the rest and pour it into the flour. Beat very thoroughly with the hand for 5 minutes. Cover the bowl and stand it in a warm place for 1 hour. Dissolve the bicarbonate of soda and salt in a little warm water and add it to the sponge mixture. Beat it up, and put it to rise again for ¾ hour. Have ready a greased girdle, moderately hot; grease some crumpet rings and let them heat on the girdle. Pour in enough batter to cover the bottom completely and allow it to cook gently until the top is set. Remove the rings, turn the crumpets over, and allow them to dry for a few minutes on the underside.

Sally Lunn Tea-cakes

12 oz. flour	1 egg
¼ teaspoonful salt	1 oz. lard or margarine
½ oz. yeast	Egg or milk and sugar to glaze
1 teaspoonful sugar	
⅓ pint milk and water	

Sieve the flour and salt into a basin. Cream the yeast with the sugar, stir in the tepid liquid, and pour the mixture into the centre of the flour. Add the beaten egg and melted fat, mix to a light, soft dough, and knead well. Divide into two or three pieces, shape into rounds, and put into small greased and floured cake-tins, half-filling them. Set in a warm place until the dough rises to the top of the tins, then bake in a hot oven (450° F.) for 15–20 minutes. A few minutes before they are ready to be taken out of the oven, brush the tea-cakes over with a little beaten egg, or with milk and sugar.

Rum Baba

8 oz. flour	4 oz. margarine
¼ teaspoonful salt	4 oz. currants, candied peel and chopped nuts
½ oz. yeast	Hot rum syrup
½ teaspoonful sugar	Mock cream and glacé fruits (optional)
¼ pint warm milk	
4 eggs	

Sieve the flour and salt into a bowl. Cream the yeast and sugar and add the warm milk. Pour the mixture into the centre of the dry ingredients and sprinkle flour on top. Put in a warm place to work for about ½ hour. Beat the eggs and add them with the melted fat to the mixture, beating well with the hand. Brush a large border mould or some small ones with melted fat, and put in the currants and chopped peel and nuts. Half-fill the moulds with the yeast mixture, cover, and put in a warm place until the mixture rises to the top of the tins. Bake in a moderate oven (375° F.) for about ¾ hour, then turn out and prick the surface. Pour over some rum syrup (made by heating 4 oz. sugar with ¼ pint water, a squeeze of lemon juice, and rum to taste) and serve hot; or decorate with mock cream and glacé fruits and serve cold.

Croissants

1¼ lb. flour	½ pint milk and water
¼ oz. salt	1 oz. yeast
6 oz. margarine	½ oz. sugar

Warm the flour and add the salt. Melt 1½ oz. of the fat, add it to the liquid, and warm. Cream the yeast and sugar. Make a well in the centre of the flour and mix to a light dough with the yeast and liquid. Knead lightly and set to rise for about ½ hour. Knead lightly on a floured board and roll out to an oblong. Place one-third of the remaining fat in small heaps on the top two-thirds of the dough, then fold in three, turning the bottom third up and bringing the top third over it. Seal the ends with the rolling-pin and give one half-turn. Roll again into an oblong, and repeat with the two remaining portions of margarine. Roll out dough very thinly and cut into squares and then triangles, finishing with the point, and curling the ends round to form a crescent. Prove for about 10 minutes on a greased tin. Then brush over gently with beaten egg and milk, and bake in a hot oven (450° F.) for 10–15 minutes.

Scones.—A plain scone mixture can have different additions which add to the variety of this simply made dish. Scones may be cooked in the oven or on a girdle.

Oven Scones

8 oz. flour	½ teaspoonful bicarbonate of soda
¼ teaspoonful salt	1–2 oz. fat
1 teaspoonful cream of tartar (½ teaspoonful, if sour milk is used)	¼ pint (approx.) fresh or sour milk

Sieve the flour, salt, cream of tartar, and bicarbonate of soda into a basin and rub in the fat. Make a well in the centre and stir in enough milk to give a light, spongy dough just firm enough to handle. Turn it on to a floured board, knead very lightly if necessary, to remove any cracks; then roll out lightly to 1 in. thick, or pat it out with the hand. Cut rounds with a sharp cutter,

dipped in flour, or cut it into triangles with a sharp knife. Place on a floured baking-sheet, glaze if desired with beaten egg or milk, and bake near the top of a hot oven (450° F.) for 7–10 minutes till brown and well risen. Cool on a rack.

Fruit Scones.—Add 2 oz. currants, sultanas, raisins, or chopped dates to dry ingredients.

Oatmeal Scones.—Follow the same recipe, substituting 2 oz. oatmeal for 2 oz. of the flour.

Rich Afternoon Tea Scones.—Follow the same recipe, adding 1–2 tablespoonfuls castor sugar to the dry ingredients, and using 1 beaten egg with 1–2 tablespoonfuls water or milk to mix. If desired, 2 oz. dried fruit may be included, rather less sugar being used.

Plain Girdle Scones

8 oz. flour
½ teaspoonful bicarbonate of soda
1 teaspoonful cream of tartar
A pinch of salt
1½ oz. butter or margarine
½–1 oz. sugar
¼ pint milk or milk and water

Sieve the dry ingredients, rub in the fat, and add the sugar. Mix to a fairly soft dough with the liquid, then turn it on to a floured board and knead it very lightly, if necessary, to remove any cracks. Roll out ½ in. thick, cut in triangles or rounds, and place on a hot, floured girdle. Cook steadily until well risen and pale brown underneath, turn over gently and cook until the other side is browned and the centre is dry. (If desired, 2 oz. sultanas may be included: add them with the sugar.)

Drop Scones

8 oz. flour
½ teaspoonful bicarbonate of soda
½ teaspoonful cream of tartar
1–3 oz. sugar
2 eggs
¼ pint sour milk or buttermilk

Sieve the flour and raising agents, add sugar, mix with eggs and milk to a fairly thick batter. Place spoonfuls of mixture on the hot, greased girdle; keep at a steady heat, and turn scones when the bubbles burst. Cook the scones till golden on both sides, and keep them in a cloth to prevent their becoming dry and crisp. Serve them with butter and jam.

Potato Cakes

1 lb. potatoes
1 teaspoonful salt
1 oz. margarine
3–4 oz. flour

Boil, drain, and sieve the potatoes. Add salt and margarine, and work in flour. Knead the dough lightly on a floured board, roll to about ¼ in. thick, and cut into triangles. Cook on a hot, greased girdle till brown on both sides. Serve hot with butter.

BISCUITS

Biscuits are made from a pastry-like dough, and during the mixing it is therefore essential to add the liquid slowly to avoid a sticky dough which may be difficult to manage. Roll the biscuit dough out on a floured board and prick the surface of the dough to prevent rising. Bake on the top shelf of a moderately hot oven (350–400° F.). Biscuits require watching during baking, as they cook quickly. Remove from the tray as soon as they are done, and cool on a wire tray. Biscuits should be stored in an airtight tin.

Digestive Biscuits

6 oz. flour
1 teaspoonful salt
1½ oz. coarse oatmeal
½–1 oz. sugar
1 teaspoonful baking-powder
3 oz. lard or cooking-fat
Milk to mix

Mix the dry ingredients together and rub in the fat very thoroughly with the finger-tips. Mix in enough milk to give a firm dough. Turn it on to a floured board, knead it lightly, and roll out rather thinly, then cut it in rounds. Place the biscuits on a greased baking-sheet, prick them well, and bake in a moderately hot oven (400° F.) until they are lightly coloured—about 15 minutes.

Easter Biscuits

12 oz. flour
Pinch of salt
6 oz. butter or margarine
5 oz. castor sugar
1 egg
3 oz. currants
1 oz. peel
Pinch of saffron steeped overnight in a tablespoonful of milk or brandy
White of egg
Little castor sugar

Sieve the flour and salt. Cream the butter and sugar. Add the beaten egg to the creamed mixture with a little of the sieved flour. Stir in remaining flour, currants, and finely chopped peel, and mix in the saffron-flavoured milk or brandy. The dough should be softer than pastry but stiff enough to roll out.

Roll out ¼ in. thick and cut into large rounds. Place on a greased baking-sheet and bake in a moderately hot oven (400° F.) for about 20 minutes, until lightly coloured.

After 10 minutes' baking brush with beaten white of egg and dredge with castor sugar.

Shrewsbury Biscuits

3 oz. margarine
3 oz. sugar
½ an egg
Vanilla essence
8 oz. self-raising flour
1 tablespoonful water (approx.)

Put the fat and sugar in a bowl and cream together until soft and white, then gradually add the egg and a few drops of vanilla essence (or a little grated lemon rind), and work in the flour, together with enough water to form a soft, pliable dough. Roll out to about ¼ in. in thickness and cut into fancy shapes with biscuit cutters. Bake in a moderate oven (375° F.) for 15–20 minutes. Cool on a wire tray.

Shortbread

6 oz. flour
A pinch of salt
4 oz. butter (or margarine)
2 oz. castor sugar

Sieve the flour and salt, and rub in the fat. Add sugar, and then knead the mixture until it will bind together. Roll it out on a lightly floured board and form it into a round cake. Crimp edges, prick, and mark into wedges. Put on a tin lined with greased paper, and bake in a moderate oven (325° F.) for 1 hour, or until lightly brown. Cool and dust with sugar.

Ginger Biscuits

2 oz. margarine
2 oz. castor sugar
1 egg-yolk
1 teaspoonful ground ginger
2½ oz. self-raising flour
Wheat flakes

Cream together the fat and sugar and beat in the egg-yolk. Stir in the sieved ginger and flour a little at a time, and knead lightly to form a dough. Form into balls, toss these in wheat flakes, and put on a greased baking-tin. Bake in a moderate oven (375° F.) for about 20 minutes.

Chocolate Biscuits

6 oz. self-raising flour
2 tablespoonfuls cocoa
4 oz. butter or margarine
4 oz. castor sugar
A little water
Vanilla essence

Sieve together the flour and cocoa and rub in the fat very thoroughly until the mixture resembles fine breadcrumbs. Add the castor sugar and mix well. Mix to a very firm dough with a tablespoonful or so of cold water to which 1 or 2 drops of vanilla essence have been added. Turn on to a floured board, roll out ¼ in. thick, and stamp into rounds or fancy shapes. Put on a greased baking-sheet and cook in a moderately hot oven (400° F.) for about 10–15 minutes.

To finish, dust with castor sugar.

As an alternative, make the biscuits thinner, then sandwich together with chocolate butter icing, and ice with chocolate (or white) glacé icing.

Brandy Snaps

3 oz. syrup
2 oz. sugar
3 oz. butter
2 oz. flour
½ teaspoonful ground ginger or grated lemon rind
1 teaspoonful brandy (optional)

Melt the syrup, sugar, and butter and allow to cool slightly, then add the flour and ground

ginger or grated lemon rind, mixing well. Stir in the brandy and put in small teaspoonfuls, 3–4 in. apart on a well-greased tin. Bake in a moderate oven (350° F.) until well spread and just golden-brown. Allow to cool for a moment, then lift off with a palette knife and quickly roll over the greased handle of a wooden spoon. Slip off carefully. If the biscuits cool too much, and are too brittle to roll, return them to the oven for a moment to soften.

Macaroons

2 whites of eggs	1 oz. ground rice (good measure)
4 oz. ground almonds	1 teaspoonful orange flower water
8 oz. castor sugar	

To Decorate

Split almonds	Little white of egg

Whisk the whites of eggs fairly stiffly. Stir in the almonds, sugar, ground rice, and flavouring, and mix thoroughly. Cover a greased baking-sheet with rice paper and place the mixture in small heaps on the rice paper; or pipe, using a calico forcing-bag and large plain pipe, leaving room for spreading. Place a split almond on each biscuit, brush with white of egg and bake in a moderate oven (350 °F.) for about 20–25 minutes until pale golden-brown. It is important to cook macaroons rather slowly, to allow them to colour evenly and to get a good texture.

Coconut Pyramids or Cones

2 egg-whites	5 oz. desiccated coconut
5 oz. sugar	

Whisk egg-whites stiffly and fold in sugar and coconut. Pile on a greased tin (covered with rice paper if available), press into shape, and bake in a cool oven (275–325° F.) until pale fawn—about ¾–1 hour. If desired, tint mixture pink or green before shaping.

CAKES

Basically there are four different types of cake. Those made by the "rubbing-in" method, by which the fat is rubbed into the dry ingredients and the liquid is added afterwards. These are usually of the plainer variety. Richer cakes are made by creaming the fat and sugar together, adding the eggs to this mixture, and finally the flour. The third method is used for fatless sponges, where the eggs and sugar are whisked together over hot water and the flour is folded into the whisked mixture. For gingerbreads the melted fat and sugar are added to the dry ingredients.

The following rules of cake-making should be observed :

Prepare the tin by greasing with lard or clarified fat. For richer cakes and some whisked sponges line the tin with greased greaseproof paper. Collect and weigh the ingredients carefully, cream the fat and sugar very thoroughly until the mixture has a white fluffy appearance.

Avoid opening the oven door during the cooking.

To test the cake to see if it is cooked, press the centre top lightly, it should be spongy and give only lightly to the pressure.

Allow the cake to cool slightly before turning it out of the tin.

Store in a tightly covered tin.

PLAIN CAKES

Rock Cakes

12 oz. self-raising flour	6 oz. margarine
A pinch of salt	6 oz. sugar
¼ teaspoonful grated nutmeg	3 oz. currants
¼ teaspoonful mixed spice	1½ oz. chopped peel
	1 egg
	Milk to mix

Sieve the flour, salt, and spices. Rub in the fat, and add the sugar, fruit, and peel. Mix with beaten egg and just enough milk to bind. Using a teaspoon and a fork, place mixture in rocky heaps on a greased baking-sheet and bake in a hot oven (450° F.) for 15–20 minutes.

Plain Fruit Cake

8 oz. self-raising flour	2 oz. sultanas
A pinch of salt	1 oz. desiccated coconut (optional)
3 oz. margarine	2 eggs
3 oz. sugar	Milk to mix
2 oz. currants	

Sieve the flour and salt into a bowl, rub in the fat, and add the sugar. Add cleaned fruit and coconut (if used). Beat the eggs lightly and add them, with a little cold milk. The mixture should now be of a dropping consistency. Put it into a greased tin and bake in a moderate oven (350° F.) for about 1 hour. Leave for a minute or two, then turn out carefully. Place on a wire cake rack to cool.

Soda Cake

8 oz. flour	Grated nutmeg
A pinch of salt	5 oz. margarine
½ teaspoonful bicarbonate of soda	5 oz. sugar
½ teaspoonful cream of tartar	6 oz. currants
	1 egg
	Sour milk to mix

Sieve the dry ingredients, rub in fat, and add sugar and fruit. Mix with beaten egg and sour milk to a dropping consistency. Put into a 6-in. cake-tin and bake in a moderate oven (375° F.) for about 1 hour.

Note : If no sour milk is available, add 1 teaspoonful lemon juice or a few drops of vinegar to ¼ pint fresh milk.

Dripping Cake

8 oz. self-raising flour	3 oz. dripping
½ teaspoonful mixed spice	5 oz. brown sugar
A little grated nutmeg	8 oz. mixed dried fruits
A pinch of salt	1 egg
	Milk to mix

Sieve the dry ingredients and rub in fat. Add sugar and fruit, mix with egg and milk to give soft dropping consistency. Put in prepared 6-in. tin and bake in moderate oven (375° F.) for 1–1½ hours.

Plain Chocolate Cake

5 oz. self-raising flour	3 oz. sugar
A pinch of salt	Milk to mix
1 oz. cocoa	Vanilla essence
3 oz. margarine	

Sieve the flour, salt, and cocoa together, and rub in the margarine. Add the sugar and mix with milk and a few drops of vanilla essence to a soft consistency. Put into a prepared 5- or 6-in. cake-tin and bake in a moderate oven (375° F.) for about 40 minutes.

RICH CAKES

Queen Cakes

4 oz. butter or margarine	½ teaspoonful baking powder
4 oz. sugar	A little milk if necessary
2 eggs	2 oz. sultanas
4 oz. flour	

Thoroughly cream the fat and sugar and add the eggs a little at a time, beating well. Fold the sieved flour and baking-powder into the mixture, together with a little milk if necessary, to give a soft dropping consistency. Add the prepared fruit, and place in spoonfuls in greased patty tins. Bake them in a moderately hot oven (400° F.) for 15–20 minutes, until firm to the touch and golden-brown in colour.

Walnut Layer Cake

6 oz. butter or margarine	2 teaspoonfuls coffee essence
6 oz. sugar	A little milk
3 eggs	Coffee walnut butter cream
6 oz. flour	American frosting
½ teaspoonful baking-powder	Walnuts to decorate

Cream fat and sugar and beat in eggs one at a time. Fold in sieved flour and baking-powder and add essence, with a little milk if necessary to give a soft consistency. Put into three prepared sandwich-tins, and bake in a moderate oven (375° F.) for 35–40 minutes, then cool. Sandwich the cakes together with coffee walnut butter cream, coat with white American frosting, and decorate with halved walnuts before the frosting sets firmly.

Rich Chocolate Cake

4 oz. butter or margarine	1½ oz. cocoa
6 oz. castor sugar	1½ teaspoonfuls baking-powder
2 eggs	A pinch of salt
Vanilla essence	About ½ pint milk
8 oz. flour	

Cream together the fat and sugar, and beat in the eggs and a few drops of vanilla essence. Sieve the flour, cocoa, baking-powder, and salt, and add to the mixture, together with enough milk to give a soft dropping consistency. Put into a prepared 7-in. tin and bake for 1–1½ hours in a moderate oven (375° F.). When the cake is cool, it may either be dredged with icing-sugar or coated with white glacé icing and decorated with chocolate butter cream, piped in an attractive design.

Madeira Cake

8 oz. flour	5 oz. butter or margarine
A pinch of salt	3 eggs
1 teaspoonful baking-powder	Milk to mix
A little finely grated lemon rind	A few drops of lemon essence
5 oz. sugar	Citron peel

Sieve dry ingredients, add rind, cream sugar and fat together until light and fluffy, then beat in the eggs a little at a time. Add the sieved dry ingredients to the creamed mixture, alternately with a little milk and the essence. Put in prepared tin and lightly add slices of peel (or put on top as soon as cake sets). Bake 1–1½ hours in moderate oven (350° F.).

Cherry Cake

8 oz. flour	6 oz. butter or margarine
¼ teaspoonful salt	6 oz. sugar
½ teaspoonful baking-powder	2 eggs
3 oz. glacé cherries	Vanilla essence
	Milk to mix

Sieve the flour, salt, and baking-powder, and add the glacé cherries, cut into quarters. Cream together the fat and sugar, and beat in the eggs one at a time; add a few drops of vanilla essence. Add the dry ingredients, and mix lightly with a little milk. Put into a prepared tin and bake in a moderate oven (350° F.) for about 1 hour.

If desired, before baking the cake put a few halved cherries on top of it, and sprinkle with castor sugar, to give a crisp, sugary surface.

Dundee Cake

6 oz. sultanas	½ teaspoonful baking-powder
3 oz. currants	6 oz. butter or margarine
3 oz. candied peel	6 oz. sugar
3 oz. blanched almonds	3 eggs
9 oz. flour	Milk to mix
¼ teaspoonful salt	

Prepare the fruit and slice the peel finely. Chop the almonds, reserving about ½ oz. for the top of the cake.

Sieve together the flour, salt, and baking-powder. Cream together the fat and sugar, and beat in the eggs one at a time. Add the dry ingredients, and mix with a little milk, if required, to give a stiff dropping consistency. Put the mixture into a prepared 8-in. tin and place the halved, blanched almonds on top. Bake in a moderate oven (350° F.) for 1½–2 hours, until firm to the touch.

Rich Fruit Cake

1 lb. currants	6–8 eggs
8 oz. raisins	12 oz. flour
1 lb. sultanas	A pinch of salt
6 oz. mixed peel	2 teaspoonfuls mixed spice
4 oz. glacé cherries	Grated rind of 1 lemon
4 oz. shelled almonds	Lemon juice
10 oz. margarine	A little mik
10 oz. castor sugar	

Clean fruit and chop peel and cherries. Blanch and chop almonds. Have all other ingredients ready. Warm margarine slightly, if hard, but do not over-heat. Cream with sugar until soft and light. Break the eggs separately into a basin, beat lightly, and add one by one to creamed mixture. Beat each egg in very thoroughly before adding next. The mixture should be light and fluffy. Sieve dry ingredients into a bowl, add fruit and rind. Fold gradually into creamed mixture. Continue to mix in dry ingredients lightly, adding a squeeze of lemon juice and a little milk. Put the mixture, which should be of a stiff dropping consistency, into a lined 9-in. tin. Bake the cake for 4½–5 hours in all, first at 350° F. for about 2 hours, and then at 300° F. Decorate if required.

SPONGE CAKES

Sponge Cake

4 eggs	4 oz. flour
6 oz. castor sugar	

Put the eggs and sugar in a large basin, stand this over a pan of hot water, and whisk the contents very briskly, until light and fluffy—the mixture should be stiff enough to retain the impression of the whisk for a few seconds. Remove from the heat. Sieve one-third of the flour over the mixture and fold in very lightly, using a metal spoon. Add remaining flour in the same way. Pour mixture into a 7-in. cake-tin, greased and dusted with sugar and flour. Bake in a moderate oven (350° F.) for about 1 hour.

Jam Swiss Roll

3 eggs	1 tablespoonful hot water
4 oz. sugar	Castor sugar
4 oz. flour	Warmed jam

Put eggs and sugar in a large basin and stand this over hot water. Whisk the mixture as in recipe above. Sieve one-third of flour over surface of mixture and fold in very lightly, using a metal spoon. Add rest of flour in same way, and stir in hot water. Pour mixture into prepared Swiss roll tin, tipping to allow it to spread over surface; bake in a hot oven (425° F.) for 7–9 minutes, until golden-brown and well risen. When the sponge cake is cooked, turn it out on to paper which has been liberally sprinkled with castor sugar. Remove the paper from the cake. Using a sharp knife, quickly trim off the crisp outer edges of the cake. Spread with warmed jam, make a cut almost through the sponge 1 in. from near edge, and begin to roll. Now roll the sponge as tightly as possible, using the paper to help manipulate it. Put the roll on a wire cake-rack and leave it until cold.

Genoese Sponge

3 oz. butter or margarine	½ oz. cornflour
2½ oz. flour	3 large eggs
	4 oz. sugar

Clarify the butter and sieve the flour and cornflour. Put the eggs and sugar into a large basin, stand it over a saucepan of hot water and whisk briskly until the mixture is light and thick, and stiff enough to retain the impression of the whisk for a few seconds. Remove the basin from the heat. Sift about half of the flour over the surface of the mixture, and fold in very lightly. Add the remaining flour in the same way, alternately with the cooled clarified butter. Pour into a shallow greased and lined tin. Bake in a moderate oven (375° F.) until golden-brown and firm to the touch, the time depending on the depth of the cake—about ¾ hour.

Note: Genoese sponge must be very lightly mixed, or the fat will sink and cause a heavy cake.

This mixture may be used as a foundation for layer cakes and iced cakes and also for a variety of iced and decorated petits fours, etc.

GINGERBREADS

Gingerbread

1 lb. flour	½ teaspoonful salt
1½ teaspoonfuls ground ginger	8 oz. brown sugar
2 teaspoonfuls baking-powder	6 oz. butter
½ teaspoonful bicarbonate of soda	¾ lb. treacle or syrup
	½ pint milk
	1 egg

Sieve dry ingredients. Warm sugar, butter, and treacle, without over-heating. Warm milk and beat egg. Combine all ingredients, mixing very thoroughly. Pour into a greased and lined tin and bake in a moderate oven (350° F.) for about 1½ hours, or until the centre is firm to the touch.

Parkin

8 oz. flour
8 oz. medium oatmeal
2 teaspoonfuls ground ginger
½ teaspoonful mixed spice
A pinch of salt
½ teaspoonful bicarbonate of soda
4 oz. dripping
8 oz. treacle
4 oz. brown sugar

Sieve the dry ingredients into a bowl and mix well. Melt the dripping, treacle, and sugar in a saucepan and stir into the dry ingredients. Pour into a well-greased and lined square tin, and bake in a moderate oven (325° F.) for about 1 hour.

CAKE ICINGS

Royal Icing

1 lb. icing sugar
About 2 egg-whites
A few drops acetic acid

Sieve the icing sugar several times if at all lumpy. Make a well in the centre and stir in the lightly beaten whites of eggs. Add the small quantity of acetic acid and continue to beat vigorously until the icing is opaque and smooth.

Glacé Icing

½ lb. sieved icing sugar
A few drops of flavouring essence
3 tablespoonfuls warm water
Colouring, if required

Put the sieved icing sugar and flavouring in an enamelled saucepan and add the water very gradually over a gentle heat. Stir till warm. Do not let the icing get too hot, or it will become crystallised. It should be thick enough to coat the back of a spoon. If too thin, more sugar should be added, or more water if too thick. Add colouring and use at once.

Butter Icing

3 oz. butter or margarine
6 oz. sieved icing sugar
Vanilla essence
Colouring, if required

Cream the fat, add the sugar by degrees, beat until smooth and creamy, then add the flavouring and, if required, the colouring.

Coffee essence may be used in place of vanilla.

Almond Icing

1 lb. ground almonds
1 lb. icing sugar
2 eggs
1 teaspoonful vanilla essence
Juice of 1 lemon

Mix ground almonds and sugar together. Beat the eggs lightly and add them, with the flavouring essence and lemon juice, to the dry ingredients. Mix to a paste and knead well.

PRESERVES

Jam must be made from fresh sound fruit, and when possible 1 lb. of sugar should be allowed to each pound of fruit. For fruit that is not rich in pectin it is necessary to add either a proportion of fruit rich in this essential or a little acid—usually citric or tartaric acid or lemon juice.

The fruit is first simmered to extract the pectin, and the sugar is then added. The jam is boiled and stirred until setting point is reached. The jam can be tested for setting by any of the following methods:

Pour a little jam on to a cold saucer. If a skin forms and wrinkles to the touch the jam is set.

When the jam falls in flakes and not drops from a wooden spoon it is set.

A thermometer can be used to find out the setting point, the average temperature being 220° F. Stir the jam evenly before the temperature is taken.

When the jam is ready to set pour it into clean, hot jars and cover at once with a waxed disc.

Black-currant Jam

4 lb. black-currants
2 pints water
4 lb. sugar

Remove the stalks, wash the fruit, and put it into a preserving-pan with the water. Simmer gently until it is tender and the contents of the pan are somewhat reduced. The skins of black-currants are usually very tough, so it is important to cook the fruit thoroughly, until tender. Then add the sugar and stir until dissolved. Bring to the boil and boil briskly until the jam sets when tested on a cold plate. Pot and cover immediately.

Strawberry Jam

(Using red-currant juice to increase bulk and aid setting)

1½ lb. red-currants
2 lb. strawberries
2 lb. sugar

Wash the currants, put them in a pan with a little water, simmer gently until tender, then pass them through a hair sieve to obtain the juice. Pick over the strawberries and put them in a pan with the currant juice and boil gently until tender. Add the sugar, stir until dissolved, and bring to the boil. Boil for about 10–15 minutes and test for jelling. Cool for 15 minutes before potting, to prevent the fruit from rising in the jars. Cover as usual.

Apricot Jam

1 lb. dried apricots
3 pints water
2½–3 lb. sugar
The juice of 1 lemon (or ½ teaspoonful citric or tartaric acid)

Wash the apricots thoroughly, put them into a basin with the water, cover, and leave to soak for at least 24 hours. Then put them into a preserving-pan with the water in which they were soaked and the lemon juice or acid. Bring to the boil, and boil gently for ½ hour, stirring occasionally. Add the sugar, stir until dissolved, and boil until the jam sets when tested on a cold plate: stir almost constantly after the sugar is added. Pot and cover immediately.

Cherry Jam

(Using citric or tartaric acid)

4 lb. Mayduke or Morello cherries
¼ oz. citric or tartaric acid
3 lb. sugar

Stone at least two dozen cherries and remove the kernels. Put the kernels in a saucepan with the cherries and acid, and cook over a low heat to begin with; then bring to simmering point and simmer for ½ hour, or until the cherries are tender. Add the sugar, stirring while the contents of the pan come to the boil; boil fairly briskly for 10 minutes, then remove the stones. Test on a cold plate for jelling. As soon as it sets, pot in hot sterilised jars and cover immediately.

Note: As cherries are lacking in pectin the jam is only of light set.

Gooseberry Jam

6 lb. slightly under-ripe gooseberries
2 pints water
6 lb. sugar

Put the fruit and water into a pan. Heat slowly at first, and as the fruit gets soft break it with a spoon. Continue cooking until the contents of the pan have reduced by approximately one-third. Add the sugar, previously warmed in the oven, and stir until it dissolves, skimming if necessary. Boil gently for 15 minutes, then test on a cold plate for jelling. As soon as the jam sets pot and cover immediately.

Plum Jam

3 lb. plums
½ pint water
3 lb. sugar

Wash the fruit and cut in halves, removing the stones. Crack the latter to obtain the kernels. Put the water, kernels, and plums in a pan and bring very slowly to boiling point: simmer gently until the fruit is cooked. Add the sugar, stir until dissolved, and bring to the boil. Boil hard for about 10–15 minutes and test for jelling. Pot and cover as usual.

Note: If the plums are ripe, less water is required.

Raspberry Jam

3 lb. raspberries
3 lb. sugar

Place the fruit in a pan, heat gently at first (adding a very little water, if necessary), then simmer until the fruit is tender. Add the sugar, stir until dissolved, and bring to the boil. Continue to boil for about 15 minutes, or until the preserve jells on testing. Pot and cover as usual.

The principles of jam-making apply also to jelly-making, in particular, pectin, acid, and sugar must be present in the correct proportions. The fruit is boiled until it is soft and pulpy before being strained through a jelly bag, and allowed to drip overnight. The sugar is added to the juice, which is then boiled until a set is obtained.

Apple Jelly

4 lb. sharp apples
Juice of 1 lemon
Water
Sugar

Windfalls can be used successfully, but sweet dessert apples do not contain sufficient pectin to produce a good set. Wash and remove any bruised or damaged portions, and cut into thick slices without peeling or coring. Put them in a pan with the lemon juice, and sufficient cold water to cover—2 quarts is approximately the amount required. Put over a low heat, bring to the boil, and simmer slowly until the apples are reduced to a pulp; then strain through a jelly cloth, leaving for several hours to drip. Measure the juice and put into a preserving-pan, with ¾–1 lb. of sugar to each pint. Bring to the boil, stirring meanwhile until the sugar has dissolved, and continue to boil briskly for 10 minutes. Test on a cold plate for jelling. Skim, pot, and cover immediately.

Blackberry or Bramble Jelly

4 lb. blackberries
¼ oz. tartaric acid
½ pint water
Sugar

Wash the berries, which should not be over-ripe, and pick them over. Put them with the acid and water into a preserving-pan and bring to the boil. Cook slowly for 1 hour, or until the fruit is quite tender, mashing it occasionally. Strain through a jelly cloth. Measure the extract into a preserving-pan, add 1 lb. sugar to each 1 pint, stir until dissolved, and bring to the boil. Allow to boil briskly without stirring about 10 minutes, then test for jelling. Pot and cover at once.

Quince Jelly

3 lb. quinces
2½ pints water
½ teaspoonful tartaric acid
Sugar

Wash the fruit, remove and discard the core and pips, and cut into small pieces or mince. Put into a strong pan, with the water and tartaric acid, and stew slowly (this is most important) with the lid on the pan, mashing from time to time, until the fruit becomes tender. If necessary, more water must be added. When the pulp is tender and fairly thick, strain through a scalded jelly bag. Weigh the extract, put into a preserving-pan, and bring to the boil. Add an equal weight of sugar, and stir while it is coming to the boil again. Boil briskly for 10 minutes, then test on a cold plate for jelling. As soon as it sets remove from the heat, skim, pot, and cover immediately.

Red-currant Jelly

3 lb. red-currants
¾ pint water
Sugar

Wash the fruit, but do not remove the stalks, and put into a preserving-pan with the water. Place over a very low heat and simmer gently until the fruit is thoroughly cooked and all the berries pulped. Strain through a jelly bag and allow to drip for several hours. Measure the extract, put it into a pan and bring to the boil. Add 1 lb. sugar to each pint of extract. Then cease stirring, allow it to boil briskly for about 7–10 minutes, and test for jelling. When the preserve jells pot and cover as usual.

Marmalades are made from citrus fruits, and as the skins are tough, prolonged boiling is required to soften the shredded skins, for this reason more water is added.

Seville Orange Marmalade

5 large or 6 small Seville oranges (about 2 lb.)
4 pints water
1 lemon or ½ teaspoonful citric or tartaric acid
4 lb. sugar

Wash the fruit and cut it into shreds. Leave in a basin with the water overnight. Put the contents of the bowl into a deep saucepan or preserving-pan, bring slowly to boiling point, add the acid, if used, and simmer gently until the peel is soft and the contents of the pan reduced almost by half; this will take about 1½ hours. Add the sugar, stir until dissolved, and then boil rapidly until a good set is obtained when a little marmalade is tested on a cold saucer. Allow to cool a little, and pour into hot, sterilised jars. Cover at once with waxed circles and then tie down.

Sweet Orange Marmalade

2 lb. sweet oranges
½ teaspoonful citric or tartaric acid
4 pints water
4 lb. sugar

Shred the oranges and put with the acid and water into a pan. Simmer gently until the rind is tender and the contents of the pan considerably reduced. Add the sugar, stirring until dissolved, and boil rapidly until a jell is obtained when a little of the marmalade is tested on a cold plate. Pot and cover as usual.

Grapefruit Marmalade (Thick)

3 grapefruits (each weighing 10–12 oz.)
4 medium-sized lemons
½ oz. tartaric acid
9 pints water
5 lb. sugar

Wash the fruit thoroughly, cut it in half and squeeze out the juice. Shred the pith and rind thinly, but discard the cores and pips. Put the prepared rind and pith, the juice, tartaric acid, and water into a large pan or bowl. The next day boil in a preserving-pan slowly until the contents are reduced by half; this will take about 3 hours. Add the sugar and stir while bringing to the boil. Boil for 10 minutes, or until it jells when tested. Pot and cover as usual.

PICKLES AND CHUTNEYS

Spiced Vinegar for Pickles

To 1 quart of vinegar allow:

¼ oz. blade of mace
¼ oz. allspice
¼ oz. cloves
¼ oz. stick cinnamon
6 peppercorns
¼ oz. root ginger (if a hot pickle is liked)

Tie the spices in muslin, place in a covered pan with the vinegar, and heat slowly to boiling point. Remove from the heat, leave to stand for 2 hours, and remove the spices before using.

Pickled Cabbage

Use red cabbage. Remove the outer leaves and shred finely. Place in a deep bowl, sprinkling the layers with dry salt, and leave for 24 hours. Drain, cover with cold spiced vinegar, and leave for a further 24 hours, mixing occasionally. Pack and cover as usual.

Pickled Onions

Use small pickling onions. Remove the skins carefully, without cutting the onions, wash, cover with brine, and leave for 24 hours. Drain, wash and dry, put into jars, and cover with cold spiced vinegar. Seal as usual.

Piccalilli

3 lb. green tomatoes
1 cauliflower
2 cucumbers
1 lb. onions
Salt
8 oz. sugar
½ oz. turmeric
1 oz. mustard
1 teaspoonful mustard seed
1 quart vinegar
1 teaspoonful peppercorns

Cut up the vegetables into small pieces and place in layers in a basin alternately with layers of salt. Let stand overnight and then drain. Boil together the vinegar, sugar, turmeric, and mustard, together with the mustard seed and peppercorns

tied in a muslin bag. Add the vegetables and heat through without boiling. Remove the muslin bag, pack the pickle into sterilised jars, and seal. Store for about a month before using.

Green Tomato Chutney

3 lb. green tomatoes	½ oz. mustard seed
½ oz. salt	½ teaspoonful pepper
4 oz. prunes or sultanas	½ teaspoonful mixed pickling spice
6 oz. chopped onion	4 pints vinegar
6 oz. chopped apple	
6 oz. sugar	

Wipe or wash the tomatoes and remove the stalks and stalk ends. Chop them small or pass them through a mincing-machine, then put them into a basin in layers with the salt, cover, and leave to stand overnight. Soak the prunes also, if used. The next day drain off the liquid and turn the tomatoes into a preserving-pan. Stone and chop the prunes and add to the tomatoes, with all the other ingredients. Cook slowly, stirring occasionally, until reduced to a soft pulp; the time required will be about 2 hours. Then pot and cover.

Marrow Chutney

3 lb. marrow	2 tablespoonfuls salt
¾ lb. shallots	12 peppercorns
¾ lb. green apples	½ oz. bruised root ginger
¾ lb. sultanas, if available	4 oz. sugar
	1½ pints vinegar

Cut up the marrow, place in a basin, sprinkle with the salt, and leave for 12 hours; drain and rinse thoroughly. Peel and chop the shallots and apples finely and add the sultanas. Tie the spices in muslin. Put all the ingredients in a saucepan, bring slowly to the boil, and simmer gently until the chutney is cooked and of the correct consistency. Pot and cover.

Note: Cinnamon and allspice may be added to this chutney, if liked.

FRUIT BOTTLING

Fruit for bottling must be in perfect condition. It should be washed and packed tightly into clean preserving-jars. The patent lids and rubber rings must be examined carefully before sterilising takes place. Water or syrup made from water and sugar is used for bottling. The average proportion for syrup is 6–8 oz. sugar to 1 pint of water. To prepare this, boil the sugar and water in a covered pan for 1 or 2 minutes and then strain through muslin.

Sterilisation by one of the following methods is carried out to destroy any moulds or bacteria.

Sterilising under Water

After the fruit has been packed in the bottling-jar, cover it with cold water or syrup. Put the tops and rubber bands in position and adjust metal clips or screw bands. Screw bands should be given one half-turn back after they have been screwed on to allow for expansion of glass during the sterilisation. Place the bottles in a deep vessel, standing them on wooden slats or a similar "false bottom," taking care that they do not touch each other. Fill the pan with cold water to come at least to the neck of the bottles. Heat gently to required temperature, taking approximately 1½ hours to reach this point. Maintain temperature as shown in the following table. Remove the bottles from the water and tighten screw bands. The next day remove bands or clips and test for a seal.

Time and Temperature Chart for Sterilising Fruit

(For use when bottling fruit by sterilising under water.)

Fruit.	Temperature to which water should be raised in 1½ hours (in degrees Fahrenheit).	No. of minutes this temperature should be maintained.
Apples	165°	10
Apricots	165°	10
Blackberries	165°	10
Cherries	190°	10
Currants (black, red or white)	180°	15
Damsons	165°	10
Gooseberries	165°	10
Greengages	165°	10
Loganberries	165°	10
Mulberries	165°	10
Peaches	165°	10
Pears	190°	20
Plums (ripe, whole)	165°	10
Plums (under-ripe or halved)	165°	20
Quinces	190°	20
Raspberries	165°	10
Rhubarb	165°	10
Strawberries	165°	10
Tomatoes	190°	30

Sterilising by the Oven Method

Pack the fruit in the jars, cover each with patty tin, and stand on a baking-tin in a cool oven (240° F.). Leave for about ¾ hour, or until the fruit has shrunk, changed colour, and appears cooked. If the shrinkage is considerable fill one jar up from another and replace in the oven for 5–10 minutes. Remove the jars one by one from the oven and fill to the brim with boiling syrup or water. Put on rubber bands, tops, and clips or screw bands. Leave before testing as before.

Vegetable Bottling

Vegetables may be preserved by bottling, provided a pressure cooker is used to sterilise them. They should be prepared according to type, and blanched before being packed into jars. Blanching is done by tying the vegetables in muslin and plunging them into boiling water for a few minutes, and then plunging into cold water. For sterilising follow the directions given in a reliable pressure-cooker instruction book. The following table shows the times required for blanching and sterilisation:

Table for Blanching and Sterilising Vegetables

Vegetable.	Blanching time.	Sterilising time (1 pt. bottles, 10 lb. pressure).
Asparagus	2–3 minutes in boiling water	30 minutes at 240° F.
Broad beans	2–3 minutes in boiling water	35 minutes at 240° F.
Beetroot	10–30 minutes in boiling water	35 minutes at 240° F.
Carrots	10–15 minutes in boiling water	35 minutes at 240° F.
Celery	5 minutes in boiling water containing ½ level teaspoonful citric acid per quart	30 minutes at 240° F.
French beans or runner beans	3 minutes in water at 180° F.	35 minutes at 240° F.
Mushrooms	Stew in a casserole	30 minutes at 240° F.
New potatoes	5 minutes in boiling water (remove skin first)	40 minutes at 240° F.
Peas (fresh)	1–2 minutes in boiling water	40 minutes at 240° F.
Vegetable macedoine	According to the individual types	40 minutes at 240° F.

IV. REFERENCE TABLES

Basic Proportions

Pastry

Suet Crust. 1 lb. flour, 2 teaspoonfuls baking-powder, 6–8 oz. suet, cold water to mix.

Short Crust. 1 lb. flour, 8 oz. fat, cold water to mix, pinch of salt.

Flan. 1 lb. flour, 10 oz. fat, 1 teaspoonful sugar, 1 yolk of egg, cold water to mix.

Flaky. 1 lb. flour, 10–12 oz. fat, pinch salt, lemon juice, approx. ½ pint cold water.

Rough Puff. 1 lb. flour, 8–12 oz. fat, pinch salt, lemon juice, approx. ½ pint cold water.

Puff. 1 lb. flour, 1 lb. butter, lemon juice, salt, cold water to mix.

Hot-water Crust. 1 lb. flour, ¼ lb. fat, salt, ½ pint milk or milk and water.

Steamed Puddings

Suet. 4 oz. flour, 4 oz. fresh breadcrumbs, 1 teaspoonful salt, 4 oz. suet, 2 oz. sugar, approx. ¼ pint milk to mix.

Plain Sponge. 8 oz. flour, 2 teaspoonfuls baking-powder, 2–3 oz. fat, 1 oz. sugar, milk or milk and water to mix.

Sponge. 3 oz. fat, 3 oz. sugar, 1 egg, 5 oz. flour, 1 teaspoonful baking-powder.

Batter Puddings

Yorkshire Pudding and Pancakes. 4 oz. flour, 1 egg, salt, ½ pint milk.

Coating Batter. 4 oz. flour, 1 egg, salt, ¼ pint milk.

Milk Puddings

Powdered Grain. 1 pint milk, 1½ oz. grain.
Ground Grain. 1 pint milk, 1½ oz. grain.
Whole Grain. 1 pint milk, 1½ oz. grain.

Custard

Baked. 1 egg, ½ pint milk.
Steamed. 1 egg, ¼ pint milk.
Cup. 1 egg, ¼ pint milk.

Cakes

Plain. 1 lb. flour, 4–8 oz. fat, 4–8 oz. sugar, 4–8 oz. fruit, 2–4 eggs, 2–3 teaspoonfuls baking-powder, ¼ teaspoonful salt, milk to mix.

Rich. 1 lb. flour, ½–1 lb. fat, ½–1 lb. sugar, 4–8 eggs, 1 teaspoonful baking-powder, ½–3 lb. fruit, milk to mix.

Sponge. 1 egg, 1–1½ oz. sugar, 1 oz. flour.

Gingerbreads. 1 lb. flour, ½ teaspoonful salt, 1½ teaspoonfuls ground ginger, 2 teaspoonfuls baking-powder, ½ teaspoonful bicarbonate of soda, 8 oz. brown sugar, 6 oz. margarine, ¾ lb. treacle, ½ pint milk, 1 egg.

Sauces

Pouring. ½ oz. fat, ½ oz. flour, ½ pint liquid.
Coating. 1 oz. fat, 1 oz. flour, ½ pint liquid.
Panada. 2 oz. fat, 2 oz. flour, ½ pint liquid.

Homely Measures

Flour, Cornflour, Cocoa, Custard Powder	2 level teaspoonfuls.	¼ oz.
	1 level tablespoonful	½ oz.
	2 level tablespoonfuls	1 oz.
	1 teacupful	3½ oz.
	1 breakfast cupful	5 oz.
Sugar, Rice, Lentils, etc.	1 tablespoonful	1 oz.
	1 teacupful	6 oz.
	1 breakfast cupful	8 oz.
Breadcrumbs, etc.	2 level tablespoonfuls	¼ oz.
Liquids	1 teacupful	¼ pint
	1 tumblerful or breakfast cupful	½ pint

British Standard Measures

Cup Measures

A British Standard Cup contains 10 fluid ounces, *i.e.*, one half-pint, a Standard Tablespoon ⅝ of a fluid ounce. Standard Measures should be filled level.

Flour	1 cup . . .	5 oz.
Semolina	1 cup . . .	6½ oz.
Sugar (granulated)	1 cup . . .	8 oz.
Fat	1 cup . . .	8 oz.
Breadcrumbs (fresh)	1 cup . . .	2½ oz.
Liquid	1 cup . . .	½ pint
Golden Syrup	1 cup . . .	1 lb.
Sultanas	1 cup . . .	6 oz.

American Standard Measures

These are based on the American pint of 16 fluid ounces. For a recipe given entirely in cup measurements use either British or American Standard Cups, provided the same measuring system is used throughout.

Avoirdupois and Liquid Measures

Avoirdupois

16 drs.	1 oz.
16 oz.	1 lb.
28 lb.	1 qr.
4 qrs.	1 cwt.
20 cwt.	1 ton
14 lb.	1 stone
8 stone	1 cwt.
112 lb.	1 cwt.

Liquid Measures

4 gills	1 pint
2 pints	1 quart
4 quarts	1 gallon

Note: 1 pint of water weighs 1¼ lb.

Liquids

Boiling	212° F.
Simmering	200–210 F.
Slow simmering	180–190° F.
Blood Temp. (also called tepid and lukewarm)	98·4° F.

Cooking Temperatures

Ovens

Slow oven	275–325° F.
Moderate oven	325–375° F.
Moderately hot oven . .	375–425° F.
Hot oven	425–475° F.
Very hot oven	475–500° F.

Electric Cookers

With thermostatically controlled electric ovens it is usually found that the thermostat scale is marked either in degrees Fahrenheit or in Numbers 1, 2, 3, etc., corresponding with 100° F., 200° F. 300° F., etc.

Gas Ovens

THERMOSTATIC SETTINGS FOR WELL-KNOWN MAKES OF GAS COOKERS

Name of stove.	250° F.	300° F.	350° F.	400° F.	450° F.	500° F.
Radiation New World "Regulo"	¼–½	1–2	3–4	5–6	7–8	9–10
Main Cooker "Mainstat" . .	¼–½ or AB	1–2 or C	4 or D	6 or F	8 or G	10–11 or J
Parkinson Stove "Ajusto" .	I	3	4–5	6	7–8	8–9
Flavel Kabineat "Thermo tat"	B	C–D	E–F	G	H–I	J
New Herald "Thermostat" .	½	1–2	4	6	8	10–11
Newhome "Autokook" . . .	½–1	1–2	4	6	8–9	10
Cannon Champion "Autimo" .	¼–½	1–2	3–4	6	8–9	11

Note: Most new gas cookers will have thermostats showing standard markings as follows:

Setting	¼	½	1	2	3	4	5
° F.	241	266	291	313	336	358	379
Setting	6	7	8	9	10	11	12
° F.	403	424	446	469	491	513	536

V. HOUSEHOLD HINTS

6. STAIN REMOVAL

The following general rules and the ready reference chart below may help to solve this difficult problem :—

1. Stains should be tackled soon after they occur, for if left they are apt to set and become more difficult.

2. Check up on the nature of the staining matter and the type and colour of the material. It is wisest to try the simplest method of removal first.

3. When dealing with delicate or coloured material, first try out the treatment on a hidden corner.

4. Short, repeated treatments are less likely to cause damage to the fabric, so be patient and very persistent.

5. Be sure to remove thoroughly the chemical used for treating the stain, or the fabric may be damaged. (Grease solvents, of course, evaporate without further treatment.)

6. Handle the chemicals carefully, especially those, such as oxalic acid and salts of lemon, which are poisonous.

COMMON STAINS AND THEIR TREATMENT

Stain.	Treatment.
Acid	Sponge with warm water to which a little ammonia has been added.
Blacklead	Sponge with turpentine, and then wash in the usual way.
Blood	Soak in cold salt water (1 teaspoonful to 1 pint) for about an hour. Wash in cool, soapy water. Any resistant or old stains will require to be treated with oxalic acid or salts of lemon solution (see Iron mould).
Candle grease	Scrape off "crust" and then sponge with cleaning benzine.
Cocoa	Treat as for tea stain.
Cod-liver oil	Treat as for grease marks, and wash if possible. Any remaining stain will need to be bleached with hydrogen peroxide (20 vol. diluted 1 part in 5 of water). Soak 10–15 minutes and wash in the usual way.
Coffee	Treat as for tea stain. If non-washing material rub in a little glycerine, removing any excess with methylated spirits. (Test rayons before treating.)
Creosote	Sponge with benzole or eucalyptus oil.
Fruit	Treat as for tea stain.
Grass	Sponge with methylated spirits.
Gravy	Sponge with a grease solvent and wash in warm, soapy water. Rinse well.
Grease	Lay the stained area over a pad of absorbent material, and dab sparingly with grease solvent, such as carbon tetrachloride. Start well outside the mark and work towards the centre, in order to prevent "ringing." Shake to hasten evaporation. Avoid inhaling the fumes of carbon tetrachloride, and keep the bottle tightly corked.
Ink :	
Writing ink	*Washable Fabrics* should be rinsed immediately in cold water. Any remaining trace of stain will require a bleach as follows : *White Linens and Cottons :* Apply a solution of chlorine bleach immediately over the mark. After a few minutes rinse thoroughly and boil. *White Silk and Wool :* Use a warm solution of oxalic acid or salts of lemon (½ teaspoonful to ½ pint) in place of chlorine bleach. Remember that these chemicals are poisonous. *Coloured and Delicate Fabrics :* Treat first with a solution of potassium permanganate (½ teaspoonful to ½ pint water) applied immediately over the mark. After a few minutes rinse away with cold water. The remaining brown stain should be removed by treating with a solution of hydrogen peroxide (20 vol. diluted 1 part to 5 parts water), acidified with ½ teaspoonful of vinegar. Rinse well.
Red ink	*Washable Materials* should be soaked in warm water to which a liberal amount of borax has been added. Wash and rinse, then bleach any remaining stain with a solution of hydrogen peroxide. *Unwashable Materials* should be sponged with methylated spirits. (Test rayons.)
Green ink	*Washable Materials* should be washed in warm, soapy water and treated with a strong solution of household ammonia. Rinse well. This treatment is not suitable for woollen or delicate fabrics.
Marking ink	Most types contain aniline dye and are very resistant : repeated treatment with permanganate solution followed by oxalic acid solution (½ teaspoonful to ½ pint water) is generally effective (see Writing ink).
Indian ink	Very resistant stain ; a solution of citric acid is sometimes effective.
Copying ink	Rub oleic acid into stain and leave for 15 minutes, then dip in ammonia solution, rub well and rinse.
Ball-point-pen ink	Sponge with methylated spirit. (Test rayons before treatment.)
Iodine	Treat with solution of washing soda or a solution of photographic hypo. (1 tablespoonful to ½ pint water.)

Stain.	Treatment.
Iron mould	Treat with a warm solution of oxalic acid or salts of lemon (¼ teaspoonful to ½ pint). After a few minutes rinse thoroughly. Handle acids carefully.
Mildew	Treat alternately with potassium permanganate solution and oxalic acid (see Writing ink). These marks are very resistant, and short, repeated treatments are necessary.
Nail polish	Sponge with acetone. (Test rayons before applying, and on no account use on acetate rayons.)
Nicotine	Sponge with methylated spirits. (Test rayons.)
Paint :	
Enamel	Treat with turpentine or white spirit.
Cellulose	Treat with acetone or amyl acetate. (Test rayons first.)
Oil paint	Treat with turpentine or benzine.
Paraffin	Treat with cleaning benzine.
Rust	Treat as for iron mould.
Scorch	Wash with soapy water containing borax, then gently rub in a little glycerine and wash again. A mild oxidising agent, such as hydrogen peroxide, is helpful, but there is no remedy for bad scorch marks.
Sealing wax	Sponge with methylated spirits.
Shoe polish	Sponge with methylated spirits or wash in warm water to which a little ammonia has been added.
Soot	Treat with carbon tetrachloride.
Tar	Scrape off tar and treat immediately with benzol or eucalyptus oil.
Tea	*White Materials:* Stretch the stained area over a basin, damp and sprinkle with borax. Pour through hot water from a kettle. Push the stained area into the solution and leave to cool. Rinse, wash, and finish in usual way. *Coloured Materials:* Sponge with a warm solution of borax (½ oz. to ½ pint). Rinse well.
Transfers	Sponge with methylated spirits. (Test rayons first.)
Varnish	Sponge with methylated spirits. If this fails try turpentine or white spirit.
Whitewash	Sponge with vinegar and water.
Wine	Treat as for fruit stains.

HOW TO PREVENT ACCIDENTS IN THE HOME

An average of twenty-four people die in their homes every day from accidents; and in addition tens of thousands enter hospital and at least 2 million cases are dealt with by out-patients departments. Doctors are agreed that most home accidents could be avoided; and the Royal Society for the Prevention of Accidents offer the following twenty pointers to home safety. Accidents fall into four main groups: falls; burns and scalds; poisoning; and suffocation.

1. Check the fabric of the house periodically for defects, repairing worn steps, broken sash cords, loose tiles or floorboards, etc.

2. Provide adequate, if not generous, lighting throughout the house.

3. Guard against fires by regular cleaning of chimneys and flues, by checking grates, stoves, gas and electric and paraffin heaters for defects.

4. Use well-designed, firmly fixed fireguards on all fires.

5. Do not use paraffin or petrol on sulky fires; or draw up fires with newspapers; or use inflammable solvents for cleaning anywhere near a source of flame. Keep matches away from children.

6. Call in experts to deal with gas or electrical defects of all kinds.

7. Provide extra handrails on staircases, outside steps, in toilets, and bathrooms when there are elderly or infirm people in the house.

8. Use non-slip floor polish. Keep floor coverings in good repair, well tacked down, and stair rods firmly fixed.

9. Avoid inflammable fabrics when possible Always use fireguards and keep mantelpieces clear of clocks, mirrors, or anything which might tempt people to go too near the fire.

10. Arrange a sensible domestic routine with a "clear up as you go" plan, thus avoiding undue haste and fatigue.

11. Train the family to be tidy.

12. Guard hot liquids. Choose well-balanced saucepans with heat-resisting handles, safety kettles, and teapots with safety devices to keep lids in position.

13. Where there are toddlers in the house turn saucepan handles and kettle spouts away from the front of the stove, and turn tablecloths under.

14. Check gas taps for looseness, use safety taps where possible, never sleep with gas fires on.

15. See that all medicines are clearly labelled and kept in a locked medicine chest. Dispose of unused medicines or pills by burning or pouring down W.C.

16. Keep all linaments, rubs, lotions, etc., for external use on a separate shelf in the medicine chest, or in a special place for safety.

17. Keep household poisons under lock and key, or on a high shelf.

18. Use safety straps in high chairs, prams, and cots; use only small, firm pillows for babies, and always hold in the natural position (*i.e.*, breast-feeding position) for a feed; never leave a baby to feed itself from a bottle.

19. Use electrical apparatus with discretion never take portable appliances into the bathroom use earthed plugs and sound flex. Switch off power at point as well as apparatus when not in use.

20. Remember that good housekeeping and common sense will protect against Home Accidents.

(A booklet called *Fire! Fire!* written to help to avoid the dangers of fire, is issued by H.M.S.O. at 4*d*.)

Wines

Wine is the naturally fermented juice of the grape. Wines differ vastly with regard to the time required for ageing; most reach ripeness for bottling 6–12 months after fermentation. The flavour of a wine depends not only on the species of grape used, but also amongst other things on the methods of fermentation and the different salts contained in the soil where the grape is grown. Therefore the quality and flavour of wines vary greatly from vineyard to vineyard as well as from country to country. Theoretically, sweet wines are produced by halting the process of fermentation before all the sugar in the grapes has been converted into alcohol; similarly, if most of the sugar is converted, a dry wine will result. In fact, much of the sweet wine sold is artificially sweetened. Fortified wines are made by the addition of brandy in the case of sherry, port and Madeira, and of a liqueur in the case of vermouth; this addition is made primarily not to strengthen the wine but to ensure stability. Sparkling wines are produced by bottling before fermentation has finished, a special type of cork being necessary to retain the CO_2 gases formed in the bottle.

The principal wine-producing countries, in order, are: France (including Algeria), Italy, Spain, Rumania, Portugal, Argentina, U.S.S.R., Greece, Jugoslavia, Hungary, U.S.A., Germany, Chile, Bulgaria, Tunisia, South Africa, Turkey, Austria, Brazil, Australia, Switzerland, Morocco, Uruguay, and Czechoslovakia. Not all of these countries produce wine for export, and France, for instance, exports less than she imports for home consumption, chiefly from Algeria.

Nobody would wish to deny that the best French wines are beyond compare, but it would be foolish to ignore the fact that there are now many other wines available here which can be compared favourably with French wines at a similar price. These are likely to prove extremely popular with what we can term the "new class" of wine-drinker, and some notes of interest may be found in the alphabetical list below of countries which are now exporting to us wines in the cheaper categories.

There is no doubt that in Britain we have been drinking more wine since the War; this is perhaps due in part to habits acquired by our troops whilst in France, Germany, and the Mediterranean countries, and partly to the increase in visits by tourists to these countries. In the wine-producing countries one drinks the local wine, red or white (seldom both), at all times and with all meals as a matter of course, and only rarely wine from another region. In Britain, one is offered today an almost limitless choice governed only, alas, by one's purse, and this choice is not rendered any easier by the fact that wine-drinking seems to have become inextricably associated with ceremony and snobbery. The ordinary beverage wine for which one acquired such a taste in the *bistro* or *trattoria* was usually placed on the table in a carafe with as little ceremony as the jug of water here But in this country much of the pleasure is destroyed by the ritual of wine-waiter in attendance, sometimes long after the meal has appeared, pouring the wine and waiting for the embarrassed diner to taste it and pronounce his approval. And if the price is not enough to discourage him, there are a hundred and one little rules of wine etiquette for him to observe if he is not to be damned for all time in the eyes of the person who "knows about wine." Small wonder then if the diner-out decides to forget the whole thing. In public-houses the picture is even more desolate for the wine-lover. The brewers, it might be argued, have a case for not wanting to promote the sales of wine as opposed to beer, but one wonders, if spirits, liqueurs, and soft drinks, why not wine?

The home is, after all, the best place for wine. As already stated, there is available today a wonderful choice of wines from a great variety of countries which are suitable for drinking at home and which do not cost a great deal more than bottled beer or "vintage" cider. These require the minimum of preparation, and will not need decanting, unless it is not intended to consume the whole bottle at one sitting, in which case it is better to open a half-bottle, as the wine will not be so nice the following day, and will probably be undrinkable after a period of more than a few days (these remarks do not, of course, apply to fortified wines). Red wines usually require to be served at room temperature, about 60° F., and can be brought to the required temperature by standing the bottle in the room with the cork drawn for a period up to an hour; do not attempt to warm by placing near the fire, as this will increase the acids, and both flavour and digestion will suffer. Most white wines are best at around 50° F. and can be kept in a cool place or, in hot weather, stood on ice or under running water. The pale, dry sherries also benefit greatly from being served slightly chilled.

A word of warning as to price: the duty on table wine bottled in this country is 2*s.* 2*d.* per bottle, 4*d.* less for an Empire wine and nearly twice as much if it was bottled in the country of origin (6*s.* 4*d.* for fortified wines, 1*s.* 8*d.* less if they were produced in the Empire). In addition, it must be reckoned that the costs of bottles, corks, handling, packing, transport, etc., add up to nearly 2*s.* per bottle, so that with a bottle of wine costing 6*s.*, 2*s.* will represent the cost of the wine and the merchant's profit. If we deduct 4*s.* therefore from the price of a bottle of wine we arrive at approximately the cost of the wine to the merchant, and it requires no very lively imagination to grasp the fact that he will be able to sell for 8*s.* a wine for which he has paid twice as much as that which he can sell for 6*s.*, and therefore that the value which the buyer can get for his money is quite disproportionate if he is prepared to pay a few shillings more than the very cheapest obtainable. Here, then, is a short guide to the various wines now available to the discerning purchaser:

FRANCE

The two main varieties of French wine are Bordeaux and Burgundy, both of which can be either red or white. The system of classification of Bordeaux wines seems particularly complicated for the amateur, but a little application will bring its own reward. The wine-producing regions are divided into various areas, and Bordeaux wines are grouped first according to the district from whence they come. The best wines are those which are named with the prefix *château* (vineyard), signifying that they are unblended with the wine of any other vineyard, and these will go on improving for many years in the bottle, whether *château*-bottled or bottled in England. Here already, one must not allow one's common sense to be affected by the snobbery prevalent in the trade; there are more than three thousand *châteaux* (*clos* and *domaines*) in Bordeaux, and therefore it follows that a good deal many more than the dozen or so well-advertised ones will be excellent; also that whereas *château*-bottled claret is not necessarily better than the same wine bottled by a good merchant in Britain, it is unfortunately a fact that it is more expensive, since it comes under a different rate of duty.

Many of the vineyards of France, in common with the rest of Europe, were replanted with native vines grafted on immune stocks from California in 1879 after being ravaged by *Phylloxera*, a plant-louse which came from

America. Curiously enough the remedy also came from America, the vine stocks there being immune to this insect. The better known white wines from Bordeaux include Graves, Entre deux Mers, and Sauternes (including Barsac). All of these names cover numerous varieties, but Graves is usually medium to dry, and Sauternes medium to sweet. In contrast to some of the Burgundies, no sugar is added to the sweet wines of the Sauternes; possibly the most famous is Château d'Yquem.

Red Bordeaux wines are called claret in this country and are light, dry, and, at their best, delicate in flavour and bouquet. Claret needs more time to mature than Burgundy, and will continue to age longer. As wine stocks evaporated during the war years and the vintages of the 1930s were generally disappointing, one must go back to the 1920s to find an exceptional claret suitably matured. St. Julien, Médoc, Fronsac, red Graves, and St. Estèphe are all clarets obtainable in the cheaper categories. St. Emilion is probably the heaviest of the Bordeaux wines, this and Pomerol being more akin to Burgundy in character. Château Cheval Blanc and Château Petrus are top-priced wines in these respective categories. *Vin rosé* is probably the Bordeaux wine which was first called claret (*clairet* = clear) in this country. *Rosé* wines are made from black grapes by fermenting the wine with the skins until the required colour is obtained. The juice is then drawn off from the skins to finish fermentation. The cheaper *rosé* wines may have been made by blending white and red wines.

The most famous white Burgundies are probably those from the Montrachet area, comprising three vineyards, Chevalier Montrachet, Le Montrachet, and Bâtard Montrachet. A hyphenated name, such as Puligny-Montrachet, denotes not a vineyard but a parish and will be a blend of wines from that parish. Famous, too, is Chablis, divided into four qualities: *grand crû* (unblended and from the best vineyards), *premier crû* (a blend of wines from the best vineyards), Chablis and Petit Chablis, lesser blends in order of merit. Mention must be made, too, of Meursault (produced a "mouse jump" away from the red wine district), and Pouilly-Fuissé, which comes from the Mâcon area and should be drunk young.

Red Burgundies are full-bodied and of slightly higher alcoholic content than clarets, though possibly of less subtle flavour. One of the best wines produced in the Beaujolais area is Moulin à vent, as it is the only one made with the superior Pinot Grape instead of the Gamay; like most Beaujolais, this wine should be drunk young. It is usually false economy to purchase the very cheapest kinds of Burgundy. Apart from the names mentioned, likely wines in the medium-price range should be available from Mâcon, Santenay, Chambolle-Musigny, Chambertin, Nuits St. Georges, and Corton (Côte de Beaune), amongst many others. The system of petty proprietorship makes possible wide variations in quality in all these vineyards, and, generally speaking, the better wine will be the more expensive one. Some excellent wines from the Loire are to be had, but more famous are those from the Rhône. 1952 was a particularly good year, and 1953, also good, is now ready for drinking and can be bought in the medium-price range, the names to remember being Châteauneuf du Pape (red), Tavel rosé, and Hermitage (red or white); Chante Alouette is a white Hermitage of most distinctive flavour.

It remains to mention the French sparkling wines. Champagne, one of the world's most famous wines, comes only from the area round Reims and is a white wine made from black grapes, the skins being excluded from the fermentation process. France also produces sparkling wines, red and white, from Bordeaux and Burgundy.

GERMANY

The very best white wines from Germany are perhaps second to none. In the middle and higher price ranges some incomparable wines are to be found among the Hocks and Moselles. The great post-war years were, of course, 1949 and 1953. Again we have a system of naming after the vineyard as well as the district. In addition, some indication as to quality is given on the label by the words *Feinste Auslese*, *Feine Auslese*, and *Auslese*, meaning that the bunches of grapes were specially selected, *Beerenauslese*, the berries of each bunch, *Goldbeerenauslese*, the ripest berries of each bunch, and the ultimate *Trockenbeerenauslese*, made from over-ripe, half-dried grapes (such a wine, if encountered, will be something of a collector's item). *Spätlese* means late vintaged, but it does not necessarily follow that the late gathering has succeeded in producing very good quality. *Original-Abfüllung* means that the wine has been bottled by the growers, who are guarantors of its quality. An *Abfüllung* relates to a firm, it may be British, which has bought wine from the growers and bottled it in its own cellars. *Naturwein* means that no sugar has been used to make it and that it is a pure grape product, but this guarantee, important for diabetics, is covered by *Original-Abfüllung* or the grower's name.

Hock (from Hochheim) is the white wine from the Rhineland-Palatinate and elsewhere in the tall, slender brown bottle while Moselle comes in a green bottle (bottlers in the United Kingdom are not above causing confusion by occasionally reversing the procedure). The Stein wines from Lower Franconia are sold in square flagons (*Bocksbeutel*). The cheaper Hocks are apt to be somewhat acid in character, while the more expensive ones are usually expected to have a faint trace of sweetness. The great Rhine wines come from the smallest district, the Rheingau; these include Schloss Johannisberg and Schloss Vollrads. "Liebfraumilch," a name originally applied to wines made around the church of that name in the town of Worms, may now be applied to any wine "of good quality and pleasant character" according to the definition of the Worms Chamber of Commerce in 1910. Dienheim, Nierstein, Rüdesheim, and Oppenheim are well-known place-names which may appear on the labels, and the wines from the Nahe Valley and Rhine-Hesse are often surprisingly good. The good Moselles are dry without being the least bit sour (the German adjective is *herb*) and most distinctive in character; they are light wines with plenty of bouquet, and are drunk young in contrast to the great Rhine wines, which will improve with age. Berncastel, Wehlen, and Zeltingen are among the famous names here, but the wines from the tributaries, the Saar and the Ruwer are not to be ignored; these are sharper in flavour, but may be of even higher quality than those from the Moselle itself. The study of some of the names applied to German wines is rewarding in itself; the more imaginative include the "Ungeheuer" (monster) of Forst, the "Gerümpel" (rubbish) of Wachenheim, and the "Lump" (ragamuffin) of Escherndorf; in addition there is the allegedly salacious appeal of "Liebfraumilch," already mentioned, and the "Kröver Nacktarsch."

With the possible exception of the "Affentaler Spätburgunder," with the monkey in relief on the bottle, there are no German red wines to acquire international reputation, though a certain amount is produced, largely in the Ahr valley, for home consumption; it is usually drunk new. We must, however, mention Sekt, the German equivalent to Champagne (both white and pink varieties are produced) and the well-known sparkling Moselles.

ALSACE

Though geographically part of France, Alsace produces wines akin to the hocks and Moselles of Germany; the best are outstandingly good, and many of great charm and individuality are available in the medium-price categories. They are named according to the species of grape used, *e.g.* Pinot, Muscat, Sylvaner, Riesling, and Traminer ("Gewürztraminer," sometimes seen on a label, is identical with Traminer, a "spicy" flavour being characteristic of this type of wine), sometimes coupled with the name of the vineyard, village, or shipper. *Grande Réserve* and *Réserve*

are terms used by the Alsatian wine-growers to correspond to *Feinste Auslese* and *Auslese* of a German wine. Although many Alsatian growers prefer to bottle their wines in their own cellars, and admittedly this provides an additional guarantee of quality, it is possible to find excellent wine which has been imported here in cask and is correspondingly cheaper.

ALGERIA

The reputation of Algerian wine in this country has never recovered from the influx of inferior-quality wine, inexpertly stored, shortly after the War. Nevertheless, more Algerian wine (under various labels, as Algeria is in any case technically a province of France) is consumed here today than is generally realised. In fact, much good wine is produced in Algeria and as labour costs are much lower than in France proper, it may offer, price for price, the better value of the two in the more modestly priced categories. Some of the wine being offered at a few shillings more than the very cheapest obtainable is particularly enjoyable.

AUSTRALIA

Australian viticulture has had the benefit of a great deal of publicity lately, so one must be ready to concede that good Australian wines may at any rate be enjoyed on their home ground. Although we have been familiar with the ferruginous Burgundies in their impossible-to-store flagons for a number of years, it seems that only these and the very cheap, sweeter table and dessert wines are generally available here in the U.K., though the Hocks and drier Sherries are worth going to some trouble to track down.

AUSTRIA

Few of the famous vineyards are left in what remained of the Austrian Empire after the First World War, but quite a variety of the drier white wines (*e.g.*, Riesling, Traminer) are available here in the medium-price categories. One of the great features of life in Vienna, of course, was, and still is, the "Heurigen," the tasting of the potent new wine in the inns on the slopes of the Vienna Woods, and there can be few who have experienced this whose judgment of these wines will not be affected by a special sort of sentimentality!

CHILE

Ancient European vines existing in uniquely disease-free conditions in volcanic soil, with opportunities for sun-ripening and cheap labour possibly greater than those existing in any European country, are among the reasons why wines can be obtained at almost rock-bottom prices from this distant country. None should be below average for the price, and some are of high quality. Several types are available here under French and German names; the "Chambertin" and "Stein wine" are recommended, and the former can be "laid down" for a few years with good effect.

CYPRUS

Some excellent bargains, notably the indigenous Commandaria, can be obtained from Cyprus by those with a taste for the sweeter dessert wines. Large quantities of sherry, both dry and sweet, are also imported and are, we imagine, the very cheapest obtainable.

GREECE

Dry and sweet table wines, as well as the sweet "muscatel"-type dessert wines from Samos, can be found; Marco and Tegea, the pink wine from Arcadia, may be sampled, but Retsina, the resinous Greek national wine, is a (hardly ever) acquired taste, and presumably is imported for the benefit of the Greek population of these islands.

HUNGARY

The most internationally renowned of Hungarian wines is Tokay, made from Io Furmint grapes left on the vines until partially dried. The best qualities take years to develop and are said to go on improving for centuries. Tokay varies from dry to sweet, but the flavour is always quite distinctive. Prices will depend on the vintage, but need not be excessive even for some which may be older than the consumer. It is usually estate-bottled, and comes in a smaller bottle than one would expect, but it compares in price quite favourably with, say, sherry or Madeira and, although not a fortified wine, can on occasion make a welcome change from these. Also available and warmly recommended are the Balatoni Riesling and Furmint and the light, dry red "Bulls' Blood" (Egri Bikaver), all costing only a few shillings more than the cheapest wine obtainable.

ITALY

Italy produces 200 types of wine, some of which have achieved great popularity in this country since the War, though some people will be familiar only with Chianti in the attractive straw-covered *fiaschi*. Tuscany produces the lighter-bodied Orvieto as well as Chianti, and both wines come in red and white varieties. When one has presented all one's friends with lamp-stands made from these flasks it is well worth-while looking around for these wines bottled in England in ordinary bottles, thus avoiding the expensive freight charges and additional duty. Various brands of Chianti, as well as the more modestly named "Tuscan table wine," can be bought this way at the very cheapest prices, and will be much appreciated by those with a taste for a slightly rough, dry wine to accompany meals. Also from Northern Italy are Nebbiolo, Piedmontese Riesling, Barolo, and Barbaresco. Valpolicella is a dry red wine from the hills near Verona with a characteristic bite; prices will vary according to the year, with the years 1949 and 1953 commanding a few more shillings at present, though none of the Italian wines mentioned is in the expensive category. Verdicchio, Soave, and Frascati are whites which will repay sampling, some exceptionally dry wines to be found under the last-named label. The island of Ischia produces large quantities of wine held in great esteem locally and on the mainland. From the Naples area also comes Lacrima Cristi, of subtle flavour and bouquet; the name is applied to a great many varieties, red and white, but generally speaking the price will have most bearing on the quality. Sicily produces Marsala, a sweet dessert wine which became well known in England after the Napoleonic wars, later to be superseded in general favour by sherry, port, and Madeira. Sardinia, besides several table wines of local repute and the dessert wine called Malvasia (supposed to be the original form of Malmsey), produces the unique and extremely potent *apéritif* Vernaccia, which we have not yet succeeded in encountering beyond its native shores. Italy also produces several delightful rosés, and the sparkling wine is Spumanti.

JUGOSLAVIA

The important vineyards north of Lubliana and round Zagreb, formerly famous in the Hapsburg Empire, now come into this category and also those around Pola and the Capo d'Istria. Wine is also produced farther south, in Bosnia and Herzegovina. The several varieties of Riesling, Sylvaner, and Traminer now available represent excellent bargains, and it is worth-while trying for those which cost a few shillings more than the cheapest obtainable.

PORTUGAL

Portugal is chiefly known in this country for the dessert wines Port and Madeira, both with traditional ties with England. "Port" is one of the few names in the wine trade protected by law, and can be applied only to wine which comes

from the Douro valley, has been fortified with Portuguese brandy, and shipped from Oporto. Tawny and ruby ports are matured in cask, and if kept too long in bottle will throw a sediment and require decanting. Crusted ports are bottled after two to three years and mature in bottle, ageing more quickly than the vintage ports, which are blends of wines from various vineyards but all of the same year, and made only in particularly good years; they are put into bottle after about two years, where they continue to mature from ten to fifty years. A matured vintage port will throw a heavy crust in the bottle so it must be decanted with care. Madeira is somewhat akin to sherry in character, but is made from grape juice which, after fermentation and before fortification, is heated to 100–160° F. in hot chambers. Madeiras are named from the grapes from which they are produced, *e.g.*, Bual, Malmsey (sweet and full-bodied), and Sercial (drier). In addition to these, Portugal has sent us recently some good, cheap table wines, including Bucellas (white) and Collares (red), though the particularly heavy and potent *vinho tinto* will not be to everybody's taste.

SPAIN

Spain's main connections with wine-drinkers in this country have always been through Sherry, the wine which first became popular in England in the sixteenth century, when it was known as "Sack" (*sec*). The only wine entitled to this name came from grapes grown at Jerez in the south-west corner of Spain and became known as "Jerez Sack," abbreviated into "Sherry." Sherry is divided into two main types, according to whether the grapes produce the white film called *Flor* during fermentation; those that do are called *Fino*, such as the dry Amontillado, and those that do not are called *Oloroso* and are sweeter. The sherries on the market today are bewildering in their variety, and selection can be only a question of personal taste. Sherry ranges from the light, exceedingly dry Manzanilla, excellent for the table as well as an apéritif, to the rich, sometimes treacly, dessert wines of "nut-brown" hue. A cheaper sweet dessert wine is the red wine from Tarragona, and Spain has recently been sending us large quantities of excellent and competitively priced table wines. Look out specially for the light claret-type Rioja wines from the upper Ebro valley and the white Alella from Catalonia, available in almost the cheapest categories. Much wine is also produced in Valencia and Alicante, though "Alicante" as the name on a label denotes a wine from Israel and "Alicant" will be Portuguese.

SWITZERLAND

Switzerland produces lighter-bodied wines of distinctive flavour, red and white. Sion Pétillant is a sparkling wine remembered gratefully, and those who have visited Liechtenstein will recall the exceptionally light red Vaduzer. Several fairly cheap Swiss white wines have become available here just recently, and these should be worth investigating.

UNION OF SOUTH AFRICA

South African Hocks and Burgundies, in particular, amongst table wines, as well as sherry in a variety of grading, offer some splendid bargains. As well as being commendable in themselves, they enjoy the advantage of the slightly preferential duty treatment.

Wine with Food

Wine at table promotes appetite, digestion, and well-being. Readers will have observed that we consider one's own personal tastes more important than what the etiquette books decree; nevertheless, the following may be useful as a rough guide:

For an apéritif—dry sherry or Champagne or a young white wine such as Moselle or Pouilly-Fuissé.
With soup—dry sherry or Madeira.
With sea-foods and white fowl—medium to dry white wine.
With steaks, roasts, chops, game and most highly-seasoned foods excepting curries—red wine.
With dessert—sweet dessert, sweet table, or sweet sparkling wine.
With cheese—port or Burgundy.
With nuts—port.
Fruit—the palate will benefit if fruit is not eaten until the wine is finished.
Coffee—coffee also should not be drunk till after the wine is finished, as it will kill the flavour of any wine.

Note that food accompanied with wine should not be dressed with vinegar.

Storage and Buying of Wines

Bottles of wine should be stored lying on their sides and tilted slightly upwards in order to keep the corks damp. Suitable racks can be bought quite reasonably, and for preference they should be kept in a cool, dark cellar, or at any rate in a cupboard away from the light.

Glasses

Text-books can be found giving elaborate illustrations of the types of glass suitable for the various wines, but in these days of limited dwelling-space and functional furniture few of us will want to bother with more than two sets of wine-glasses. One should be of the long-stemmed variety with a fairly large cup-shaped bowl; these should do service for all white and sparkling wines and should be handled by the stem to avoid raising the temperature of the wine too much. Also recommended is a set of the modern, stemless variety with a fairly large tulip shaped bowl, produced so pleasingly in Scandinavia and elsewhere. These are ideal for red wines, as the bowl can be held in the hand and the contents maintained at body temperature, and they can also be used for port and sherry as well as for spirits and liqueurs. Thin, colourless glass should be chosen so that the colour of the wine is seen to advantage, and the bouquet will be enjoyed better if the glass is not filled too full.

VINTAGE CHART

This chart, prepared by The Wine and Food Society, is for the benefit of those interested in good wine.

Year	Port	Claret	Burgundy	Rhone	Rhine and Moselle	Sauternes	White Burgundy	Champagne
1935	7	2	4	3	5	2	5	3
1936	3	3	2	5	1	3	4	2
1937	4	5	5	6	6	7	7	5

A Guide to Gardening

TABLE OF CONTENTS

A Guide to Gardening

CULTIVATION OF FLOWERS.

Throughout this section the notes must be taken to refer to cultural conditions in the British Isles, although in many cases the information can be adopted to suit the necessity of readers living abroad. Undoubtedly, in many temperate parts of the world interest in gardening has increased enormously during the past decade or so, despite the fact that numbers of large gardens have ceased to exist and that few people can afford to pay for full-time help in their gardens. To counteract this, the all important labour-saving garden has come into its own; shrubby plants have replaced annual bedding schemes and large lawns put down instead of herbaceous borders or beds of particular plants.

In addition, the owner-gardener is anxious to avail himself of the excellent selection of modern tools; thus the conventional hoe is being replaced by the "Swoe" or the Wolf pattern of Dutch weeder, both of which are very easy to use, and digging can be done quickly—and with much less effort—by using the new German tool the "Terrex" spade. For grass mowing, the work is easily done with motor mowers like the "Rotosythe," or an electrically-driven pattern.

For greenhouse work, smaller houses are being used and one, say, 12 ft. by 8 ft., can be run economically with a minimum winter temperature of 40° Fahrenheit by the introduction of trouble-free, thermostatic heaters or the turbo-heaters. At the moment, besides automatic heating, the prototypes for automatic ventilation and watering are making an appearance.

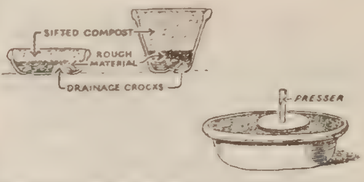
While advocating the use of such appliances, it must be pointed out that there are also to be found tools, sundries, and fertilisers of little value, and many of which have never been properly tested prior to being put on the market. It is, therefore, a good plan to discuss the comparative merits of any appliance or horticultural sundry with a competent horticulturist or to contact a public authority. In particular, many local horticultural societies have special trading facilities, and the merits of most garden things are generally known and discussed among members.

Throughout this Guide the vexed question of change in scientific name has been dealt with as liberally as possible and, whenever necessary, synonyms and cross references are given. In dealing with cultivar names, that is, varietal names like rose 'Peace,' reference is made as recommended in *The International Code of Nomenclature for Cultivated Plants* (1958). By so doing, the references are right up to date and further information on any particular plant or subject is easy to find. For the purpose, a few standard works of reference are given after each section. Normally, all the plants mentioned in the text are available through the usual trade channels.

After each plant listed there is a note on its propagation. Generally, this is the easiest or most efficient way of doing so, but it is not necessarily the only means. Details of the various methods employed are as follows:

Seed. Generally speaking, the early spring is the most suitable time for sowing seeds of trees and shrubs besides those of herbaceous plants and alpines. Where only a few plants are needed, the seed can be sown in pots and a suitable compost made up with 2 parts of soil, 1 part of peat, and 1 part of coarse sand. Before sowing, the pot should be stood up to its rim in water so that the soil is soaked. Then the seed can be sown thinly and covered with a light sprinkling of sifted compost.

For very fine seed, like begonias or azaleas, the seed must have only the merest "sugaring" of sand just sufficient to anchor it. When sown, the pots should be covered with a pane of glass (to prevent evaporation) and kept, if possible, in a warm greenhouse or frame. With this method of propagation it is important to remember that failure will result if the seed is sown too deeply, if the temperature is too low, or if the soil is too dry.



Correct Preparation of Seed Pots and Pans—Note provision for ample drainage and compost to rim of its container. After sowing, the containers are covered with a sheet of glass.

Cuttings. There are two main types of cutting: soft-wood cuttings made from fresh, green shoots in the spring and summer and hard-wood cuttings made of mature or semi-mature woody shoots in the autumn. A soft cutting is taken about 3 in. long, the lower leaves removed and a clean cut made through a node in the stem. These are then inserted in pots containing a light, sandy soil or a rooting medium such as horticultural vermiculite, well watered, and covered with a bell jar or plastic bag. Delphiniums, hydrangeas, and lupins are all propagated in this way.

Hard-wood cuttings are taken in the autumn and made from shoots about 8–12 in. long. These are inserted in a sandy soil out of doors or in a cold frame, and left to develop for a year. Blackcurrants, forsythia, and roses can be propagated by this means.

Layering. This is one of the easiest ways of propagating the majority of woody plants, and is used to increase stocks of plants like clematis, lilacs, and rhododendrons. Normally, layering is done in the autumn or spring when suitable branches are pegged down. On each of these the young shoots are, in turn, pegged down and tips turned upwards and tied in position. To encourage rooting, gritty sand and peat should be worked around each layer, and usually the young plant can be severed from the parent after about eighteen months.

Division. By this method it is easy to propagate the majority of herbaceous plants, some rock-garden plants, and a few shrubs. A few herbaceous plants, like delphinium and paeony, are slow to get established after moving, and here the method should not be employed. In any case, old plants should not be split up in a wholesale manner; instead, it is far better to select a few young healthy plants, divide these, and replant the best of the young shoots, in the autumn.

ALPHABETICAL LIST OF ORNAMENTAL PLANTS.

Abutilon.—The greenhouse species is often used in public parks for bedding schemes. *A. vitifolium*, with white, mauve, or blue flowers makes a fine wall shrub for warm gardens. If given full sun it will quickly reach 10–15 ft., but is sometimes short-lived. *Prop.*—Easily raised from seed sown in March in a warm greenhouse or frame.

Acer (**Maple**).—Hardy, ornamental trees; the Norway maple is often planted for its magnificent autumn colour and as a lawn tree. *A. palmatum* and vars. constitute the Japanese maples; all colour brilliantly in the autumn but do not grow freely unless given some shade and a light soil rich in humus. *Prop.*—Seed, layering, or budding.

Achillea (**Yarrow**).—Grey-leaved perennials for open border or, dwarf species, for rock garden. Valued as a cut flower, particularly *A. ptarmica* 'Perry's White,' with double, white flowers and *A. eupatorium* 'Gold Plate,' with large, flat, yellow flower heads. *A. millefolium* is a pernicious weed of turf (T33). *Prop.*—Division in autumn.

Acidanthera.—Scented, bulbous plant introduced from Abyssinia. It is not difficult to grow if the corms are planted in the spring and lifted in the autumn for storing in a frost-proof shed. It requires a sunny position and plenty of water in the summer. *Prop.*—Offsets removed when the old crop of bulbs is lifted.

Aconitum (**Monkshood**).—Blue-flowered perennial plants particularly useful for lightly shaded positions or full sun; flowers from May to July, height 3–5 ft.; roots poisonous. *Prop.*—Seed or division.

Adiantum.—*See* **Ferns.**

A Well-Grown Agapanthus—In winter the pot should be kept in a cold greenhouse or some protected place; in summer afforded full sun.

Agapanthus.—A bulbous plant, native of South Africa, usually found in seaside gardens and sometimes grown in tubs; flowers blue, violet, or white. It needs winter protection in the form of a covering of bracken or straw and a light soil heavily enriched with manure. Worthy of wider cultivation. *Prop.*—Seed or division in March.

Ageratum.—Blue-flowered carpeting plant. *See* **Annuals.**

Allium (**Flowering Onion**).—A genus of nearly 300 species of bulbous plants widely distributed over the Northern Hemisphere. The foliage has the distinctive smell of garlic, but some species are grown for garden ornamentation; in particular *A. roseum*, valuable late-flowering rock plant for dry positions. *Prop.*—Offsets, taken from parent bulbs in the spring.

Alstroemeria aurantiaca (**Peruvian Lily**).—This tuberous-rooted, herbaceous plant is often grown for cutting. Flowers orange-red and height 2–3 ft.; of easy culture if afforded a sunny position and left undisturbed. For best results apply liquid manure or soot water when growth starts. *Prop.*—Seed or division.

Althaea (**Hollyhock**).—A truly delightful, old-world plant, but not often seen, as modern hybrids have given way to rust disease. Best grown in a rich, heavy loam. Mulch with manure of any sort and stake as necessary. *Prop.*—Seed in June, thin out, and transfer to flowering position in September. Although a perennial, in some localities the best results are obtained by treating it as a biennial and raising a small supply annually.

Alyssum.—Low-growing annuals and perennials for rock garden and sunny border. The perennial, *A. saxatile*, is deservedly popular by reason of its bright, spring flowers and value as a wall plant. The variety 'Citrinum' is bright yellow and 'Dudley Neville' biscuit-yellow. *Prop.*—Perennial sorts by cuttings in June.

Amaryllis belladonna.—Often this plant is confused with the greenhouse, bulbous plant, *Hippeastrum*. The true amaryllis is a half-hardy bulb for planting at the foot of a warm wall; it has white to pinkish-red flowers. When planting, cover neck of bulb with an inch of soil and leave undisturbed, as the plant resents moving and is slow to get established. Lack of flowering is generally due to planting too deep. Established clumps may be fed with hoof and horn meal at 2 oz. per sq. yd. in July. *Prop.*—Divide and replant clumps in early July.

Amelanchier canadensis.—A large shrub or small tree; valuable for its spring flowers and autumn colour. As it will grow almost anywhere in sun or shade, it makes a good plant for informal screening. *Prop.*—Seed or layers.

Amepelopsis.—*See* **Parthenocissus.**

Anchusa italica.—A blue-flowered perennial with fleshy roots, growing to a height of about 3 ft. Responds to feeding and needs a position in full sun. *Prop.*—Root cuttings in the spring; division in the autumn.

Anemone.—The tuberous-rooted section includes the 'Caen' and 'St. Brigid' strains. These are best grown in an open position in light, rich soil; plant in October, lift and store when foliage dies. The hardy, fibrous-rooted perennials are varieties of *A. hybrida* (syn. *japonica*) and constitute one of the most accommodating of perennials, being particularly useful for damp, shady positions. Worthy of wider attention from gardeners. *Prop.*—Perennial sorts by division in autumn.

Annuals.—These are plants which develop from seed, flower, fruit, and die within a year. Additionally, some perennials, like antirrhinums, may be treated as annuals for the convenience of their cultivation. Sunny borders may be planted solely with annuals, they may be interplanted with perennials, used for window boxes, or, occasionally, in the rock garden. All sorts do best in well-worked, light loam enriched each year with a dressing of fish meal at 3 oz. per sq. yd., ten days before sowing or planting.

In the division of the group Hardy Annuals may be sown in the open ground as soon as conditions permit during March or April where the plants are to flower. Wet or cold soils will give many failures, and fine seed should be covered only with the lightest sugaring of soil. Often surprising—but delightful—results may be obtained by sowing broadcast mixed seed of annuals specially offered by some trade houses.

To raise Half Hardy Annuals, seed may be sown in early March in a warm greenhouse and the seedlings pricked out into boxes. Subsequently, the plants are grown on in a cold frame, gradually hardened off, and then transferred to their flowering positions towards the end of May.

Anthemis tinctoria.—Hardy perennial with feathery, grey foliage and flowers in varying shades of yellow. Height 2–3 ft., needs full sun and good for cutting. *Prop.*—Division in the autumn. *Anthemis nobilis* is the chamomile sometimes unwisely used to make lawns.

Antirrhinum (**Snapdragon**).—The popular bedding plant requiring a good soil and position in full sun now largely in disfavour owing to rust

disease; planting should be restricted to rust-resistant varieties. *See* Annuals

Aphelandra squarrosa.—An evergreen, perennial plant introduced from Brazil. Often sold as a house plant, albeit a warm temperature and a high humidity are necessary for its cultivation. When grown indoors it is best discarded when the flowers fade and the foliage starts to wither, as it cannot be successfully grown on from year to year under normal conditions indoors.

Aquilegia.—The modern race of hybrids are the result of much interbreeding with wild forms to give a wide range of colours. Best when planted in light shade where soil is naturally moist. *Prop.*—Seed in late spring; transplant to flowering position for following year.

Arabis caucasica.—Once known as *A. albida*, this common rock plant is often used on dry walls. The double-flowered form is particularly good. *Prop.*—Cuttings in July; a fresh stock should be raised regularly as the special forms tend to die out.

Araucaria (Monkey Puzzle).—This tree was introduced from Chile, where it forms large natural forests, and widely planted in Victorian days. Browning of foliage suggests lack of water in the summer or, occasionally, effects of very cold weather. It should be planted in a position protected from the prevailing wind. *Prop.*—Seed in a warm greenhouse.

Armeria maritima.—A hardy perennial with pink or red flowers in the spring; must be grown in full sun where the soil is dry. *Prop.*—Division after flowering.

Artemisia.—A genus of shrubs and perennials suitable for sunny borders or rockeries. *A. lactiflora* is among the best of the herbaceous species, having grey foliage and creamy-white flowers. *A. abrotanum* (lad's love) in the shrubby section has grey, fragrant foliage. *Prop.*—Herbaceous section by division; shrubs by cuttings in the early summer.

Arundinaria.—*See* **Bamboo.**

Aster (Michaelmas Daisy).—By careful breeding this plant has been improved out of all recognition, and many first-class varieties are available in the trade. Responsive to good cultivation, it is used for its colour late in season and properties as a cut flower, particularly *A. yunnanensis* 'Napsbury' and *A.* 'Barr's Pink.' A wide range of colours are available besides some fine, low-growing forms. In the border one pleasing combination can be made with *A.* 'Harrington's Pink' and *Scabious* 'Dinkie.' *Prop.*—The clumps should be split up *annually* in the spring, and only the plumpest pieces of outer root replanted.

Aster, China or Common.—*See* **Callistephus.**

Astilbe.—Allied to the *Spiraea* and useful for planting in moist, rich soils; flowers white, pink, and crimson; height 2 ft. *Prop.*—Division of clumps.

Aubrieta.—A name often misspelt. Throughout the country it is used as edging or for dry walls. Many lovely sorts available apart from the commonly found, pale-blue variety. It is a lime lover. *Prop.*—After flowering the plants should be severely trimmed and, as necessary, stock increased by division.

Aucuba japonica.—Much maligned and overplanted shrub, but one tolerant of neglect and sunless or smoky conditions. Interesting variants of the type, like 'Crotonifolia,' may be found in trade lists. *Prop.*—Cuttings rooted in the open in July

Auricula.—Correctly known botanically as *Primula auricula*. Flowers of alpine auriculas are white or yellow, while in those of florists' auriculas are to be found some of the most delicate colourings among hardy plants. Choice varieties are grown in pots under glass; others in moist, shady borders. *Prop.*—Seed or division in the spring.

Azalea.—*See* **Rhododendron.**

Bamboo.—The common name for the large group of woody grasses, reference to which is difficult owing to the confusion in their nomenclature. Often grown for screening and wind breaks, and is a favourite shelter for small birds; the best for home-grown canes are *Phyllostachys viridiglaucescens* and *Sinarundinaria nitida*. An interesting account of bamboo growing is found in the *Jour. Roy. Hort. Soc.* (June 1957). Growth can be encouraged by feeding with sulphate of ammonia and mulching with leaf-mould in the spring. *Prop.*—Division of clumps in late spring; transplants must be kept watered until established.

Begonia.—A genus showing wide diversity of form and much horticultural value. Of particular interest is the tuberous-rooted section, of which many of the loveliest varieties have originated in the nurseries of Messrs. Blackmore and Landon at Bath. For bedding schemes, the tubers are started in boxes of rich soil under glass in late March and planted out 9 in. apart in June. During the summer feed with liquid manure of any sort and keep moist in dry periods. *Prop.*—Cuttings in early spring in a warm case.

Berberis.—An extensive genus of beautiful and easily grown shrubs, evergeen and deciduous; the former used mainly for beauty of flower, and the latter for autumn colouring and ornamental fruits. *B. stenophylla* makes a fine evergreen hedge; invaluable for preventing illicit entry by dogs and, even, unruly children. *B. aggregata* and *B. jamesiana* are among the best berrying kinds. Prune in the winter by removing old wood. *Prop.*—Seed in spring or layering in autumn.

Buddleia.—Deciduous shrubs of easy culture for sunny positions. Varieties of *B. davidii* available in range of colours from purple to white; best when pruned hard by cutting all previous year's growth back to main stems in February. The weeping species, *B. alternifolia*, often grown as a standard; good specimens at R.H.S. Gardens, Wisley. This sort must be pruned in the summer by cutting off the dead flowering stems. *Prop.*—Cuttings in July–August in cold frame.

Cactus.—In the main grown in cool greenhouses or as house plants and, if cultivated well, many will flower every year. As a general guide, plants should be watered fairly freely in the summer and little in the winter, but there are exceptions. A detailed account of growing these fascinating plants will be found in *The Cactus Grower's Guide*, by Vera Higgings (Latimer House), 1946.

Calceolaria.—Seed of the greenhouse biennials sown in June or July for flowering in the following year. Mixed seed provides a wide range of colour. *C. integrifolia* is a half-hardy perennial, raised by cuttings or seed, for greenhouse or bedding work.

Calendula (Marigold).—This common hardy annual is freely raised from seed sown in August. Of easy culture in any sort of soil, although it is worth getting seed of new varieties now available. *See* **Annuals.**

Callistephus.—The China asters are among the best half-hardy annuals for garden and indoor decoration, but good soil and full sun are necessary for best results. *See* **Annuals.**

Camellia japonica.—Hardy, evergreen shrub rightly beloved by connoisseurs and cultivated in gardens for many centuries. May be grown in cold greenhouses, woodland gardens, and against north- and west-facing walls; under all conditions camellias must have a moist, acid soil. Best varieties for outdoors are 'Althaeaflora' (dark red), 'Donckelarii' (red, white marbling), and 'C. M. Wilson' (pink). Of recent introduction is the desirable *C. williamsii* bred from *C. japonica* in part; often the subject of television and gardening notes. The dropping of buds is thought due to dryness at the roots at some time

or sharp fluctuation in temperature. *Prop.*—Cuttings under glass in early July.

Campsis grandiflora.—Sometimes found listed as *Bignonia* or *Tecoma*; choice deciduous climber for warm wall, large reddish-orange flowers in autumn. To encourage flowering growth, prune hard back to old growth in spring. *Prop.*—Cuttings in April struck in a warm case.

Canary Creeper.—*See* **Tropaeolum.**

Candytuft.—Hardy annual (*q.v.*) and perennials with white, crimson, blue, or purple flowers. The perennial—*Iberis sempervirens*—is a fine plant for a rock wall. *Prop.*—Seed or, perennials, from cuttings.

Canterbury Bells.—*See* **Campanula.**

Carnation.—*See* **Dianthus.**

Centaurea (Cornflower).—The perennial species are valuable for cutting and border use, and may be found in such colours as pink, crimson, and yellow. *Prop.*—Lift and divide every third or fourth year. The hardy annual, *C. cyanus*, is often sold as a cut flower. *See* **Annuals.**

Cheiranthus cheiri (Wallflower).—Among the finest displays of this biennial are those found each year in the public gardens of Southend-on-Sea, where it is used in conjunction with bulbs and forget-me-nots. *Prop.*—Seed sown thinly in rows in May and seedlings thinned or lined out and then transplanted in late autumn. The so-called Siberian wallflower, *Erysimun asperum*, which has bright orange flowers, is grown in the same way, but it is intolerant of wet soils. Both sorts are lime lovers, and on acid soils plants may receive treatment with 1 oz. of lime in a gallon of water.

Chimonanthus (Winter Sweet).—Hardy, winter-flowering shrub with heavily scented flowers. Although brought to this country from the Far East in the mid-eighteenth century, its garden value is not widely appreciated. The large-flowered, yellow sort, *C. praecox*, is particularly fine, but like all the varieties, it is best grown against a sunny wall and where the soil tends to be poor. If growth is excessive and flowering poor, trim back young growth severely in March to encourage short, spur-like shoots. *Prop.*—Easily raised from seed or layers.

Chionodoxa.—Blue-flowered bulbs useful for under-planting shrubs such as forsythia. Will tolerate shade and may be left undisturbed to naturalise. Height 6 in.

Christmas Rose.—*See* **Helleborus.**

Chrysanthemum.—Hardy annual sorts are available in a wide range of colours and give a fine display in the summer months. *See* **Annuals.** There are also a number of perennials such as the shafta daisy and the oxeye daisy for sunny, herbaceous borders; all do well in ordinary soil, but should be lifted and split up about every three years. The plant sold by florists in the autumn is the Japanese chrysanthemum. Many are hardy out-of-doors, but no plant is more responsive to good cultivation and normally is best left to the specialist grower. For ordinary garden work, the best sorts are the Korean and Otley types. Under a brief reference the interesting details of cultivation cannot be dealt with fairly, and reference to specialist books is recommended.

Cistus.—Hardy and half-hardy evergreen shrubs, mainly native of Southern Europe. Well worth growing in light, sandy soils in reasonably sheltered positions. Pruning should be limited to the removal of any shoots killed in the winter. Among the hardiest sorts are *C. laurifolius*, white flowers, 6 ft., and *C. purpureus* 'Silver Pink,' 3–4 ft. *Prop.*—Easily raised from seed.

Clarkia elegans.—A Californian, hardy annual of easy culture and mixed seeds will give a wide range of colours in white, pink, scarlet, and crimson. *See* **Annuals.**

Clematis.—A hardy climber for walls, screens, pergolas, and the like. Best kinds are to be found among named varieties in nurserymen's lists. A light, well-drained soil is necessary and if fed annually with a bucketful of manure or compost the plant will thrive for many years. Occasionally plants will be found on north walls, and if grown in full sun some light protection from the sun is desirable for the roots. Varieties which flower on the *current* season's growth, like *C. jackmanii*, should be pruned in late February to within a foot of the ground; other sorts should have sufficient old growth removed, after flowering, to keep them within bounds.

Unfortunately, the climber is sometimes killed by clematis wilt, a disease about which very little is known, and the premature death of young plants should not be blamed automatically on the supplier. *Prop.*—Layering, by which means one shoot will often give three or four plants.

Convallaria majalis (Lily of the Valley).—Well-known perennial that will thrive in any damp, shady position. For best results lift every four or five years and mulch annually with old manure. *Prop.*—Division when foliage fades.

Coreopsis.—The hardy annuals are found in catalogues under "Callipsis," and all will thrive in ordinary soil. The flowers are mainly bright yellow, and many are good for cutting. *See* **Annuals.** Similarly, the perennials have the same predominant colour and are useful because of their long flowering season and abundance of flower. *Prop.*—Division.

Cornflower.—*See* **Centaurea.**

Cosmos.—Tall-growing, half-hardy annuals that are best grown in full sun in a dryish border. The large, daisy-like flowers can be had in a variety of colours, including white, yellow, pink, and crimson. *See* **Annuals.**

Cotoneaster.—Hardy evergreen and deciduous shrubs or small trees bearing scarlet or sometimes yellow berries in the autumn. All may be grown in ordinary or poor soil and planted in open or shady shrubberies and trailing species used against walls, over banks, or as ground cover. For shrubberies *C. lacteus* and *C.* 'Cornubia' with red berries and *C. rothchildianus* with yellow berries are among the best sorts; *C. conspicuus* 'Decora' is a strong grower for banks, while *C. horizontalis* is an excellent cover for any wall. Planting may be done in the autumn or spring, and no pruning, apart from occasional shaping, is required. *Prop.*—Seeds and layering.

Crataegus (Hawthorn).—There are many good varieties of our British hawthorn, *C. oxyacantha*, worthy of attention, particularly 'Coccinea' (crimson) and 'Paulii' (double, red). All will do well on poor soils, and no pruning is required. The common hawthorn makes a stout, impenetrable hedge planted 9 in. apart in a double row 9 in. asunder. *Prop.*—Common sort by seed; choice varieties by budding.

Crocus.—A hardy bulb of great beauty which was studied for many years by one of the greatest horticulturists of the twentieth century, the late E. A. Bowles. Does best in rich soil planted in bold groups around margins of beds or borders and naturalised in grass. When required, feed in early spring with bone meal at 2 oz. per sq. yd. *C. sieberi* and *C. tomasinianus* very early flowering; large-flowered, garden forms about three weeks later. *C. zonatus* flowers in the autumn and is often naturalised in grass. *Prop.*—Clumps may be lifted and divided about every five years, in July. The so-called autumn crocus is *Colchicum autumnale*. This bears large, lustrous leaves in the summer, followed by mauve or white flowers—of fleeting duration—in the autumn.

Crown Imperial.—*See* **Fritillaria.**

Cyclamen.—*See* **House plants (T39).**

Cytisus (Broom).—Only does really well in dry, poor soils in full sun; choice, procumbent sorts, like *C. kewensis*, used in rock gardens and tall ones

in open shrubberies. Pruning is important; shoots should be shortened after flowering, but old wood must never be cut. *Prop.*—Seed and cuttings in August in a sandy soil.

Daffodil.—*See* **Narcissus.**

Dahlia.—The cultivation of this plant is a special study, and there are probably more garden varieties of it than any other plant. Ordinary soil enriched with manure and an open position is required. Tubers may be planted 3 in. deep in April or young plants in late May. During the summer feed with soot water and liquid manure. After the first frosts lift, dry, and then store tubers in peat or straw in frost-proof place. Many stocks of dahlia are affected by virus (T30), and purchasers should be careful to check source of supply.

Daphne.—Shrubby plants, giving some of the most richly scented of all flowers. In particular, there is *D. mezereum*, which requires a damp soil; failure with the shrub is due usually to root disturbance or virus disease (T30) *D. odora* is one of the evergreen, fragrant species. Some references have suggested that this lovely shrub is not hardy, but there is no evidence to support the supposition. *Prop.*—Seed or layering.

Delphinium.—Hardy annuals and perennials. The latter sorts have gained popularity enormously since the War, due in the main to the activities of the Delphinium Society but also to the introduction of many very fine new varieties. American hybrids, like the 'Pacific Strain,' are very large but tend to die out and, consequently, lack the true, perennial habit of European sorts, albeit some of these have been weakened by the introduction of poor lines. It is important therefore to select stocks of strong constitution. Delphiniums need a deep, rich soil and a sunny position protected from wind. Plant in autumn 3 ft. apart, feed in the summer with liquid soot water, and mulch with decayed compost or manure in the spring. When growth starts, thin out weak growths to leave not more than five stems per plant. In winter take steps against possible slug damage (T28), and on this point it is beneficial to protect crowns with a covering of ashes. *Prop.*—Cuttings in the spring or seed; division of clumps is a poor alternative.

The hardy annual sorts are the well-known larkspurs, which grow to a height of 18 in. to 2 ft. and may be found in a range of colours including pink, red, white, and shades of blue. *See* **Annuals.**

Deutzia.—Hardy deciduous shrubs thriving in any soil and valuable for their summer flowers of white or whitish-pink shade. To keep the plants vigorous, shoots should be shortened after flowering and old or weak wood cut out. *D. scabra* is of robust habit, reaching about 7 ft., and *D. elegantissima* 'Fasciculata' proves a graceful shrub some 5 ft. tall with clusters of about twenty flowers coloured rosy-pink and each nearly an inch across. *Prop.*—Cuttings made from firm young growths about 10 in. long in sandy soil out-of-doors.

Dianthus.—This name covers a wide range of annual, biennial, and perennial plants. At one time often grown for their fragrance, but to a large extent this has been lost with the introduction of wider ranges of colour. Border carnations and picotees grown out-of-doors need a limy, fairly rich soil in full sun. Plant in the autumn or spring and, as the buds appear, feed with soot water or liquid animal manure, if necessary. These groups are *not* of good perennial habit and should be propagated annually to ensure continuation of stock.

The common pink requires the same soil conditions, and should be propagated when the stock gets weak; good scented varieties should be sought, and include the 'Imperial Pinks,' 'Mrs. Simkins,' and 'White Ladies.' *Prop.*—The best method is by layering in July so that the new plants can be put in their flowering position by mid-September. The lower leaves are pulled off selected shoots and a slit passing through a joint is made in the stem. Each layer is then pegged down with a hair-pin, the pin being placed above the cut. The layers are then covered with an inch of sandy compost and well watered.

In this genus is the sweet william; although truly a perennial, it is generally grown as a biennial and, consequently, the plant is raised from seed in May out-of-doors. In gardens where it is prone to rust disease control is most difficult and it is not worth a place.

LAYERING CARNATIONS—This is a typical example of how many plants can be propagated. A strong, new growth is pegged down into sandy soil after a cut has been made in the stem, at the point of pegging. Once rooted the layer can be severed from the parent and transplanted a week or two later.

Digitalis.—The biennial sort generally found in gardens is the common foxglove, which is grown in light shade in fairly rich, moist soil. In the past many named forms have been offered in the trade, but undoubtedly the best one is *D.* 'Sutton's Excelsior.' *Prop.*—Seed sown in May out-of-doors.

Doronicum.—Hardy perennials with yellow flowers; warrants wider planting, as they are among the earliest perennials to bloom and will thrive in poor soil or in some shade. The best is *D. austriacum* flowering in March, height 9 in. *Prop.*—Division after flowering.

Echinops.—Name appropriately derived from *echinos*, a hedgehog, in reference to the spiny, long scales of the flowers. The plant does well in an open position, where the globular heads of steely-blue flowers can be seen to advantage. *Prop.*—Division in March, but best left undisturbed as long as possible, as it must be moved with care.

Elaeagnus.—Hardy deciduous and evergreen shrubs generally grown in rather dry positions as foliage plants. Of the evergreen sort, *E. pungens* 'Aureo-Variegata' has bright golden variegation, and is therefore valuable for indoor decoration during the winter. *Prop.*—Layering in late summer.

Erica.—The heathers are native plants to Britain, and many variants found in the wild have been introduced into gardens to good purpose. Indeed, heathers have become so popular that special Heather Gardens have been made, and two fine examples may be found in the Royal Gardens, Windsor, where the planting is new and the Royal Horticultural Society's Gardens, Wisley. Here, different sorts reaching the dimensions of small trees, dwarf kinds, and many scores of interesting variants, to supply flower throughout the year, will be found.

The Scottish heather is, botanically, *Calluna vulgaris*, and, like all British heathers, it is intolerang of lime or chalk. Where alkaline conditions exist, planters can try *E. carnea*—a winter-flowering heather—or *E. darleyensis*, but the results are usually disappointing. When planting all heathers, clumps must be well firmed and after-

wards kept moist; subsequently, mulch all types annually with peat. *Prop.*—Division and layering.

Erigeron.—Hardy perennial for sunny borders; daisy-like flowers freely develop and are good for cutting. *Prop.*—Division in the autumn.

Escallonia.—Slightly tender evergreen and deciduous shrubs. In the Midlands protection of a south wall is necessary; suitable for open shrubbery in the South. Ideal for maritime conditions, and here may be used to good effect as hedges. Many of the best varieties originated in the nursery of Messrs. The Slieve Donard Co. in County Down. *Prop.*—Cuttings under a glass jar in summer; layers in September.

Eschscholzia californica.—A hardy annual of easy culture; height 18 in., flowers mainly shades of orange. *See* **Annuals.**

Everlasting Flowers.—*See* **Helichrysum.**

Ferns.—A large number of plants are included under this name and, as they grow wild in many parts of the world, some need hothouse conditions. They are distinguished from flowering plants by their method of reproduction; instead of producing seeds, ferns develop spores, usually on the back of their leaves. The hardy kinds may be grown in equal parts of leaf-mould and soil, and the fronds of leaf-losing kinds should not be removed until the spring, as they offer some protection from the cold. Tender ferns should be repotted when new growth starts in the spring in a compost of equal parts soil, leaf-mould, and sand, using a pot just large enough for the purpose. During the growing season, in particular, keep the roots moist and plants free from a dry or smokey atmosphere. *Prop.*—Division of clumps when growth starts in the spring.

Forget-me-nots.—*See* **Myosotis.**

Forsythia.—Commonly found in many gardens, as it is of easy culture in any soil. Flowers bright yellow in early spring. To keep in good shape prune directly after flowering by cutting out old wood. *F. intermedia* 'Lynwood' is upright in growth and *F. suspensa* of weeping habit; both types make good wall plants for North aspects. *Prop.*—Cuttings in the autumn.

Foxglove.—*See* **Digitalis.**

Freesia.—Greenhouse bulbous plant and, if grown for scent, care must be taken to select fragrant varieties. Pot in the autumn in a fairly rich compost and keep as cold as possible until growth is seen. Then bring into a frost-free greenhouse and water freely. When flower stems appear, feed with liquid manure; after flowering, gradually dry-off until time for repotting. Failures almost invariably traced to premature forcing before root growth has been made or growing in excessively high temperature. *Prop.*—Offsets at potting time.

Fritillaria.—The one mainly used in gardens is *F. imperialis*, a handsome, spring-flowering bulb. To grow it *really* well, this species must be given a deep, rich soil and, contrary to some views, it is best lifted every year as soon as the foliage fades. If growth is poor or plants do not flower, feed when growth starts in the following spring with equal parts of bone meal and superphosphate at 3 oz. per sq. yd. *Prop.*—Offsets removed from parent bulb at lifting time. The old bulb should then be replanted at once and any offsets lined out in a nursery row.

Fuchsia.—Greenhouse and tender flowering shrubs. The outdoor sorts (of which *F. riccartonii* is the best) may be grown in light soil in full sun. In the spring prune all growth down to ground level; protect, if necessary, in winter with covering of cut bracken or dry straw. Greenhouse varieties are potted firmly before growth starts in the spring and, when buds burst, all the previous year's growth can be cut back hard. To encourage flowering, feed with a liquid manure, such as dried blood, and syringe foliage in hot weather. During the winter keep plants dry and house in a cool greenhouse. *Prop.*—Cuttings of new growth taken about 1 in. long and inserted in sand under a bell jar.

Gaillardia.—Hardy annuals and perennials 18 in. to 3 ft. high which bear large, richly coloured flowers invaluable for cutting in mid- and late-summer. Unfortunately, on heavy soil the perennials are liable to die after flowering, and even on well-drained soils they cannot be considered long-lived plants. *Prop.*—Normally it is necessary to raise a fresh stock in alternate years; seed is sown in May in a cold frame and the young plants lined out in a reserve border prior to planting in the autumn.

Galanthus (Snowdrop).—Hardy bulbs well worth growing if given a moist, shady position where stock can be left undisturbed. Planting should be done in fairly bold clumps; bulbs are not expensive, and many variants, like double-flowered and tall-stemmed ones, are well worth a trial. *Prop.*—Lift and divide clumps in August.

Gentiana.—The gentians comprise some of the most fascinating of all rock-garden plants partly, perhaps, because some are difficult to manage. In particular, *G. acaulis*—which has true "gentian blue" flowers—is exacting in its requirements, and in many gardens flowering can never be induced. What controls flowering has not been discovered, and the plant can be grown well in acid or limy soils. On the other hand, *G. sino-ornata* must have an acid soil and is best in a position out of the direct sun. Beginners with the genus are advised to start with easily grown sorts, like *G. lagodechina* and *G. septemfida*. *Prop.*—Seed sown in cold frame in March or division in early spring.

Geranium.—The true geranium or cranesbill is a hardy floriferous perennial for rock garden or open border. In the latter case *G. ibericum* (blue flowers) and *G. sanguineum* 'Lancastriense' (rosy-pink flowers) are exceptionally good, and both do well in dry, sunny positions. The so-called "bedding" or "greenhouse" geranium is a pelargonium (*q.v.*). *Prop.*—Seed in March.

Gladiolus.—Dutch hybridists have done much work on this bulbous plant, and many new and lovely varieties are now available. The plant is responsive to good cultivation, and corms may be planted 4 in. deep and 6 in. apart during the spring in well-prepared ground. When the blooms fade remove the dead spikes of flower and lift the corms in September. After a month—and this point is important—pull off the old shrivelled corm and clean the new one. By doing this there is less likelihood of spores of diseases overwintering on the new stock. Finally, the corms should be stored in a dry, frost-free shed, and if given proper attention can be kept for a number of years. *Prop.*—Bulbils, removed when the corms are cleaned, can be sown in the spring in nursery rows and will flower within two years.

Godetia.—Hardy annual of easy culture and tolerant of poor soil conditions and even some shade. There are many varieties, mainly with bright flowers of rosy-pink and crimson. *See* **Annuals.**

Guernsey Lily.—*See* **Nerine.**

Gypsophila.—The favourite sort is *G. paniculata*, which is often grown for cutting, together with its double-flowered form, 'Bristol Fairy.' To do well gypsophila must be given a dryish soil which the roots can penetrate undisturbed; if growth is poor mulch in the spring with animal manure. *Prop.*—Generally done by seed in spring; special forms by grafting.

Hamamelis.—A lovely, but little grown, winter-flowering, heavily-scented shrub. The delicate, lemon-coloured flowers appear interminably from December to February. Although it flowers in its young stage, hamamelis is slow to get established and must be left free of root disturbance. The best sort is *H. mollis* introduced from China in 1879. *Prop.*—Usually by grafting; can be layered.

Heather.—*See* **Erica.**

Hedera.—Although ivy is seldom planted nowadays, there are a few evergreens to equal it for covering buildings. The large-leaved ivy with golden variegation, *H. colchica* 'Dentato-Variegata,' is invaluable for cold or shady walls. *Prop.*—Cuttings in August in shady border out-of-doors.

Helianthus.—The perennial sunflowers are tall, yellow-flowered plants of vigorous habit. They spread quickly and become a nuisance, and therefore clumps should be lifted and single, rooted pieces replanted every other year. The annual sunflower may reach a height of 10 ft. or so; seed is sown out-of-doors in April or seedlings raised under glass in the spring. When the flower bud appears, feed with soot water. The seed may be used as food for large birds like parrots.

Helichrysum.—Although this is a large group of plants, the most interesting is the half-hardy annual, *H. bracteatum*, the everlasting flower. When the flowers are fully developed they are cut with long stems and hung up to dry for winter decoration. *See* **Annuals.**

Heliotropium peruvianum (**Cherry Pie**).—Scented, shrubby plants used for greenhouse decoration or summer bedding. *H.* 'Sir Edward Fry' is among the scented varieties and *H.* 'Princess Marina' is the best dark-purple variety. For really good results, heliotropes need a rich soil and plenty of water in summer. *Prop.*—Cuttings 2–3 in. long in early autumn or spring, struck in sandy loam in a warm greenhouse.

Helleborus.—The Christmas rose, *H. niger*, should be planted out of the direct sun in a moist soil which has been liberally enriched with leaf-mould and old manure and here left free from root disturbance. Its large, white flowers appear irregularly from December to February with early flowering encouraged by protection with cloches. The Lenten rose, *H. orientalis*, flowers from February to April, and it is well worth searching nurserymens' lists for varieties with a wide range of colours. *Prop.*—Division of clumps in the spring, with each piece having four or five growth buds; the clumps should not be split into small pieces.

Hemerocallis.—Hardy perennial for moist border either open or slightly shaded. Mulch established clumps in the spring with compost or manure. Many new varieties are coming on the market as a result of introductions from America, where the plant is popular. *Prop.*—Division.

Hibiscus.—The evergreen, shrubby sorts with large exotic flowers are widely grown in the tropics and can be seen under glass in botanic gardens in Britain. *H. syriacus* is a deciduous, hardy species; little pruning is required, and in full sun it will reach 8–10 ft. Normally, it is a free-flowering plant of great beauty and, in cases where the flowers fail to develop, the stock is best replaced with good varieties, like 'Coeleste' (single, blue) and 'Woodbridge' (single, red). *Prop.*—Cuttings under glass; grafting.

Holly.—*See* **Ilex.**

Hollyhock.—*See* **Althaea.**

Honeysuckle.—*See* **Lonicera.**

House Leek.—*See* **Sempervivum.**

Hyacinth.—Bulbs generally used for bowl culture; often results are disappointing, but responsibility does not necessarily rest with the nurseryman, as poor cultivation is the most probable cause. Plant in September–early October (not later) in peat, loam, and sand, and keep as cool as possible until growth starts, when bowls may be brought into a warm room. Care must be taken with watering, as the bulbs must not dry out nor the compost allowed to become wet and soggy. After flowering, plant out-of-doors and lift annually in June for replanting in the autumn; for bowls a fresh stock is required every year. Failures are mostly due to late planting or faulty watering.

Hydrangea.—A favourite shrub introduced from the Far East. Of the many forms, the one offered by florists, *H. macrophylla*, is the most popular. This can be bought in a wide range of shades, from white and pink through to crimson and blue. The colour will depend on soil reaction: in alkaline or neutral soils *only* white and pink shades can be grown, and blue flowers will be found *only* on acid soil. The intensity of colour can be improved by adding lime in the first instance and flowers of sulphur in the second, but it is not possible to make an alkaline garden soil acid in reaction. Lack of flower is generally the result of buds being killed by cold weather. For this reason, hydrangeas are best not pruned until the late spring; then old flower-heads and any weak or unwanted growth can be cut out. During the summer the plants must not suffer from lack of water.

Among the many other sorts are *H. paniculata*, with large, cone-shaped panicles of flower and *H. petiolaris*. The latter plant is a vigorous climber, well suited to cover cold walls or for climbing over dead trees. *Prop.*—Cuttings in July–August in a cold frame.

Iberis (**Candytuft**).—The hardy annual sorts will thrive in any soil, and may be had in a range of colours. *See* **Annuals.** The perennial candytuft (*I. sempervirens*) is a good plant for a rock wall and has white flowers in early spring. *Prop.*—Seeds in spring and cuttings in summer.

Ilex.—The ornamental value of our native holly is rarely fully appreciated, bearing in mind that, on good varieties, the berries sometimes persist until March. The greenish flowers are sometimes bisexual, and sometimes male and female flowers are on *separate* plants. For this reason hollies should be planted in groups, and at least one plant of good berrying habit, like *I. aquifolium* 'Pyramidalis,' grown. Some varieties have yellow berries and gold or silver variegations on their leaves. *Prop.*—Seed; special forms by budding.

Iris.—This plant is divided into two main sections: those types which grow from bulbs and those which grow from fleshy rhizomes, with many subdivisions in each of them. Of the latter type, there are the commonly grown bearded flag irises, which, owing to their ease of cultivation and wide range of colours, are appropriately known as the poor man's orchid. Notwithstanding, these irises respond to good treatment, doing best in well-dug soil to which a little manure has been added and a dressing of rough chalk forked into the surface. The site should be in full sun for preference and one that never lies wet in winter. Planting or division of established clumps is done in July, setting the rhizome on the surface of the soil but firming the roots well. To maintain growth and flower, feed annually in the spring with equal parts of superphosphate and bone meal at 3–4 oz. per sq. yd. Iris gardens are not often seen nowadays, but the fine example still maintained at Kew is well worth close inspection.

In the bulbous section the Siberian iris is a graceful plant with delicate foliage, though much smaller-flowered than the flags. They make a fine waterside planting or may be grown in the herbaceous border. The Japanese iris is another water lover, and this has delicate-coloured, clematis-like flowers. On the other hand, for dry, poor stony soils in full sun the lovely, winter-flowering Algerian iris, *I. unguicularis* (*stylosa*), is an ideal plant, flowering as it does in December and January. This is a plant which must be left undisturbed after planting in June and if leaf growth is excessive the foliage can be cut back by half in August. Spanish, Dutch, and English types of bulbous iris are often used as cut flowers. These may be planted in ordinary garden soil in the autumn and left undisturbed until signs of deterioration are found.

Japonica.—Common misnomer of *Chaenomeles* (*q.v.*).

Jasminum.—The yellow-flowered, sweetly scented winter jasmine blooms intermittently

from November to February. It grows in any soil, and is best trained up a wall or grown on a trellis. Pruning consists of cutting out the flowering shoots as soon as the blossoms fade. The summer jasmine is a vigorous climbing plant with white, scented flowers. It needs a sunny position and should be well thinned after flowering. *Prop.*—Layering in summer.

Kalmia.—Hardy American shrubs with clusters of waxy, rose or pink blossoms in early summer. Although slow to get established and requiring a damp, acid soil, the plant is well worth growing. It constitutes a feature of the gardens of the National Trust at Sheffield Park, Sussex. *Prop.*—Seed or layering.

Kerria japonica.—A hardy shrub which will thrive in any garden but is best fed with manure to encourage strong growth. When the yellow flowers fade, the stock should be kept vigorous by cutting out old or weak growth. The plant is named after William Kerr, a young man despatched from Kew to collect plants in China. *Prop.*—Division in autumn.

Kniphofia (Red-hot Poker).—Although these plants are so commonly seen, their full value as late-flowering subjects is not often fully explored. There are a number of good varieties worth growing, such as 'Maid of Orleans' (white, 4 ft.), 'Mount Etna' (scarlet, 5 ft.), and 'Royal Standard' (gold and scarlet, 4 ft.). Of equal value is the dwarf variety with grass-like foliage, *K. nelsonii*. *Prop.*—Division in March; easily raised from seed if so desired.

Laburnum.—Handsome trees with long racemes of yellow flowers, the seeds of which are very poisonous. It is not advisable to remove branches, as wounds do not heal well or quickly, and once a specimen shows signs of deterioration it is best replaced with little delay. *Prop.*—Seed or grafting.

Larkspur.—*See* **Delphinium.**

Lathyrus (Sweet Pea).—For general garden decoration, seed may be sown in pots in a warm greenhouse in early February prior to transplanting out-of-doors in April. When heat is not available sowing can be done in the open in October, setting the seed 4–6 in. apart and 2 in. deep where the plants are to grow. In this case the rows are best protected by cloches. As the plants flower with great freedom and make strong growth, a rich, deep soil is required. During the summer water should be given freely and liquid animal manure or soot water applied weekly when flowering starts. When raised for exhibition, special cultural treatment is necessary. The cause of the condition referred to as bud drop is not known, but it is thought to be connected with low temperature and faulty root action.

There is also the hardy, perennial sweet pea, an old-world plant usually seen at its best in cottage gardens. This plant requires the same cultural conditions, except that the old stems are cut down in the autumn. Three or four different species are available, and all are easily raised from seed sown in the spring.

Lavandula.—The lavender is one of the best known of garden plants. It thrives in full sun in a light soil; old flower heads should be clipped off in the summer, but any cutting back into old growth must be left until the spring. The best garden form is *L. spica* 'Nana Atropurpurea'; it has a neat, dwarf habit, with deep purple flowers, and is available from leading nurserymen. *Prop.*—Cuttings out-of-doors in August–September.

Leucojum.—The spring snowflake flowers in February and is a charming plant for any damp, shady border. Although it has a large flower, it has never become as popular as the snowdrop, despite its ease of culture. It should be grown by everyone who values early spring flowers. *Prop.*—Lift clumps and replant after removing offsets in August.

Lilac.—*See* **Syringa.**

Lilium.—The lilies constitute a large genus of plants, some of easy culture, some demanding the most exacting of conditions. For a soil containing chalk two of the best lilies are *L. candidum*, the Madonna lily, and *L. regale*. The former is a feature of many gardens in South Wales, where bulbs are planted near the surface of the soil and the clumps eventually left to develop undisturbed. Only the easiest-grown lilies are suitable for the herbaceous border and, here, apart from the Madonna lily, the tiger and martagon lilies should be first choices for beginners in the cultivation of this genus. *Prop.*—Those referred to above may all be raised from seed sown out-of-doors (or in deep boxes in a cold frame) in the spring. In the following April line out into nursery rows prior to transplanting to flowering positions. Also propagated by offsets and bulbils.

Lily of the Valley.—*See* **Convallaria.**

Lobelia.—The bedding lobelias are perennial plants best raised as annuals (*q.v.*). They do well in a light soil, but should be firmed at planting time to prevent plants dying off during a hot spell. The handsome, tall-growing lobelias with scarlet flowers, like *L. fulgens* 'Huntsman,' may be used in herbaceous borders with great effect, but the roots must be lifted and overwintered in a cold frame. These sorts grow to a height of 2–3 ft. and will do well only on a wet, heavily manured soil.

Lonicera.—The honeysuckles make effective climbing plants if grown on the shady side of arches or tree stumps or against north or west walls. Care should be taken to train young growth before it becomes hard. Old shoots may be cut out each spring to keep the plant within bounds, although space must be available for free development. If growth and flowering is poor mulch the roots in the spring with old manure. *Prop.*—Easily done by layering in late summer.

Lupins.—There are two sorts of lupins, perennial and annual. The herbaceous perennials are among the most colourful of plants as a result of the famous 'Russell' strain being introduced. Of late years, however, the constitution of the plant has been weakened through, perhaps, breeding and virus diseases, and it should be taken for granted that most stocks have to be replaced every two years or even annually in some cases. The plant requires a rich soil and is best in ground free of lime. Conversely, in poor soil the tree lupin thrives and will reach a height of 7–9 ft.; plant in full sun and lightly prune into shape after flowering. *Prop.*—Both sorts are best raised from seed sown in May out-of-doors and transferred to flowering positions in October. The annual lupin may be obtained in a range of colours, and should be grown in full sun. *See* **Annuals.**

Magnolia.—Rightly said to be one of the most beautiful of all flowering plants. Contrary to popular belief, some kinds are of easy culture, flowering when young and suitable for small gardens. Of course, careful selection is necessary and for a specimen on a lawn *M.* 'Soulangeana' (large, white or white, purple-stained flowers) is ideal. *M. stellata* freely flowers in the young stage, and may be planted in an ordinary border if the soil is lime free. To encourage growth, mulch annually with peat or leaf mould, but never dig near the roots. The evergreen magnolia is often seen as a fine wall plant in old gardens. This is the only species which may be pruned, and long shoots can be cut back hard in April. There are a number of non-flowering strains of the evergreen one, and unsatisfactory plants are best destroyed, as flowering cannot be induced; in buying a replacement care is necessary in order to avoid *another* dud. *Prop.*—Seed sown as soon as it is ripe in October; layering.

Mahonia.—Hardy evergreen shrub. *M. aquifolium* is useful as ground cover, and will thrive in any soil and in any cold, shady position providing the soil is not waterlogged. *M. japonica* has long racemes of lemon-scented flowers in the winter; inferior sorts are often offered by nurserymen

under this name. *Prop.*—Seed, suckers, and layers.

Marigold.—*See* Calandula.

Mathiola.—The night-scented stock is a hardy annual with insignificant purplish flowers which open at dusk; grown primarily for its perfume. Conversely, the so-called Ten-Week stocks and a selection of these, the East Lothian stocks, have a wide range of colours. If sown in March they may be used for summer bedding or if sown in August overwintered in a sunny frame and grown as a biennial.

Brompton stocks flower earlier than the other sorts, and are grown as a biennial by sowing seed in June or early July and, after pricking out into boxes, are overwintered in a sunny frame. In mild districts, if the soil is well drained, stocks may be planted out-of-doors in the autumn, but a reserve should be kept for filling up gaps in the spring.

Meconopsis.—This genus includes the famous "blue poppy," introduced from the Himalayas. It is not a plant of easy culture, albeit large groups are grown in many woodland gardens where soil conditions permit. After flowering the plants generally die, although an occasional plant may persist. *Prop.*—Seed sown in March.

Michaelmas Daisy.—*See* Aster.

Montbretia.—This bulbous plant is of easy culture and has a long season of flowering. Many new varieties with large flowers are now available, and growth can be kept vigorous by lifting and dividing the clumps every three or four years. Plant in early spring 4 in. deep and 6 in. apart and in cold gardens protect clumps in winter with a covering of ashes.

Myosotis.—The forget-me-not is grown as a biennial by sowing seed in May and planting out in the autumn in conjunction with spring-flowering bulbs and wallflowers. Poor varieties freely establish themselves, and these should be destroyed before planting any of the really good sorts offered by seedsmen.

Narcissus.—This botanical name includes plants commonly known as "daffodil" and "narcissus." Although often grown, the wide garden value of these spring-flowering bulbs is not fully realised, as by careful selection of varieties a long season of flower can be obtained when they are grown in formal borders or naturalised. Thus, a season may be extended with 'Peeping Tom' and 'Covent Garden' (early) and 'Geranium' and 'Buttermilk' (late). The bulbs can be left undisturbed until flowering is affected by over-crowding; the clumps should then be lifted and be divided in the late summer. To maintain vigour, feed annually in February with 2 parts bone meal, 1 part hoof and horn meal, and 1 part sulphate of potash at 2 oz. per sq. yd. The chief troubles with narcissi are due to eelworm (**T29**) and the narcissus bulb fly (**T28**). For indoor work, plant in bowls in October and keep in cold place until growth is an inch high; failure is invariably due to premature forcing or faulty watering.

Nasturtium.—*See* Tropaeolum.

WATER LILIES IN TUBS—Drawing (A) shows a cross-section with correct percentage of water and soil together with water lilies and fish. Drawing (B) illustrates marginal planting with primulas, Japanese irises, and a dwarf coniferous tree.

Nepeta (Catmint).—In recent years this edging plant with silvery foliage and mauve flowers has become increasingly popular. When flowering in mid-summer there is no finer display of colour. It grows freely on any light, well-drained soil in full sun. The best sort is *N. faassenii*. *Prop.*—Division of clumps in March.

Nerine.—Lately this lovely bulbous plant has increased in popularity mainly through the varieties introduced from the late Lionel de Rothschild's garden at Exbury. The hardy sort *N. bowdenii* flowers in the autumn and should be planted at the foot of a warm wall in August or September and left undisturbed for many years. As the bulbs gradually multiply and work to the surface, a light dressing of sandy compost, to which has been added a little bone meal, can be applied. *Prop.*—Separation of bulbs in August.

Nicotiana (Tobacco Plant).—This half-hardy annual is grown mainly for its heavily scented flowers, which open in the evening. It is worth remembering that the white-flowered sorts are the best in this respect; scarlets and pinks are very much inferior. *See* **Annuals.** The tobacco of commerce is a different plant, namely, *N. tabacum*.

Nymphaea.—No branch of gardening is more fascinating than the water garden, and for it the chief plant must be the water lily. Basically, the main reason for failure is in the fact that in most pools the *average* depth of water is less than 18 in.; this means that the water is liable to be adversely

affected by extremes of temperature. All nymphaeas should be grown in full sun and where the water is still; in streams it is necessary to utilise a little backwater out of the current. Water lilies are planted in May in large wicker baskets with a compost of three-quarters of loam and a quarter of peat; alternatively, planting sites can be built up with bricks to the desired height. If growth is poor, mould Clay's Fertiliser into the size of pigeons' eggs and drop one around each clump. To maintain a healthy condition in the water, fish should be introduced as soon as the plants are established. *Prop.*—Division of tuberous roots in late May.

Orchids.—In the main, this large group of plants needs greenhouse conditions and specialised knowledge. Their cultivation has attracted the attention of some of the greatest of horticulturists, and detailed references may be found in books like *Orchids, their Description and Cultivation*, by C. H. Curtis (Putnam), 1950.

Paeonia.—There are two sorts of paeony, the tree paeony and the herbaceous paeony. The former needs a sheltered, warm position and takes about three years to flower from planting time. The latter sort needs a moist, rich soil, and should be mulched annually in the spring with well-rotted manure; some are known not to flower, and as such plants cannot be induced to do so they should be destroyed. The old-fashioned variety of paeony has been superseded by many fine new varieties found listed by specialists. *Prop.*—Tree paeonies by layering or seed sown in the autumn; herbaceous sorts by seed or division.

Pansy.—*See* **Viola.**

Papaver (Poppy).—The oriental poppy is a hardy herbaceous perennial with striking flowers, intolerant of shade and root disturbance. As it blooms early, it should be set near the back of a border, as the large leaves look untidy later in the year. Apart from the commonly grown, red-flowered sort there are others in shades of crimson, pink, and lavender. *Prop.*—A wide range of colours can be obtained by sowing mixed seeds in May. This is a better method than division. The Shirley poppy is a hardy annual (*q.v.*), while *P. nudicale* is a biennial needing a warm, sheltered position.

Parthenocissus (Virginia Creeper).—This climber, with its brilliantly-coloured leaves, makes a fine sight in the autumn, and there is no better plant for covering brickwork or unsightly buildings with a south or west aspect. It has been suggested (mainly by builders) that the plant will damage stonework or cause dampness. There is little evidence to support these suppositions, and reasons for damage can usually be traced—often without difficulty—to other sources. The plant has had a number of names—*Ampelopsis veitchii* is one—but up-to-date nurserymen are listing it correctly as *P. tricuspidata*. *Prop.*—Cuttings out-of-doors in the late summer; layering.

Passiflora caerulea (Passion Flower).—A south wall in favoured gardens is needed to grow this plant. It is of vigorous habit and, once the framework of branches has been produced, it should be pruned annually in the early spring, by cutting back all the previous season's growth to 2–3 in. of the main stem. *Prop.*—Layering.

Pelargonium (Geranium).—So-called "bedding geraniums," such as 'Paul Crampel,' are really zonal pelargoniums. To maintain a stock, take cuttings in early August and insert in sandy soil around the edge of a pot and overwinter in a frost-free greenhouse. In the spring pot-up singly and use for bedding. Otherwise pot-on after two months and, if early buds are nipped off, plants can be adopted for late flowering indoors. Pelargoniums are easy to grow, but for best results a position in full sun is necessary, and cuttings should be rooted *before* the autumn so that overwintering constitutes no great difficulty.

Petunia.—Although really perennials, these plants, native of South America, are treated as annuals (*q.v.*). They are sun lovers and do best on light soils. Petunias make fine plants for sunny window boxes, and particularly happy combinations can be made by planting together varieties such as 'Violacea' (deep violet) and 'Cheerful' (pale pink) or 'Flaming Velvet' (crimson) and 'Cream Star' (pale cream). The violet-flowered sorts are faintly scented.

Philadelphus (Mock Orange).—Although some fine varieties of this shrub are available in the trade, it is not grown as widely as its merit deserves. As a scented shrub it has few equals, while it is tolerant of poor soil conditions and shade. Particularly good sorts worth searching for are 'Albatre' (double), 'Beauclerk' (single), and 'Sybille,' which, at 3 ft., is about half the height of the others. After flowering, prune annually by removing as much old flowering wood as possible. *Prop.*—Hard-wood cuttings out-of-doors in November.

Phlox.—A wide range of varieties of the border phlox are offered to make an impressive display late in the season. If grown on light soils some shade is desirable, as phloxes do well where only the soil is damp. For this reason, mulching should be done annually in the spring with compost or animal manure. Failures are usually due to eelworm (**T29**). *Prop.*—Seeds in autumn; division.

Poppy.—*See* **Papaver.**

Polyanthus.—*See* **Primula.**

Polygonium.—In the main these plants are weeds of gardens, although originally they were introduced from the Orient for ornamental purposes at a time when their invasive habits were not fully appreciated. The one woody climber in the genus, *P. baldschuanicum*, makes an admirable cover where a very vigorous plant is wanted. Rampant and unwanted species may be eradicated by hormone treatment (**T33**).

Primula.—Polyanthuses, primroses, greenhouse primulas, and the hardy primulas all belong in this genus. The first two are the most popular; both will do well only in damp soil and respond to generous manurial treatment; both are available in a wide range of colours. *Prop.*—The Blackmore and Langdon strains of seed will give a magnificent display of mixed colours. Sow in warm greenhouse in early March or cold frame in April; prick out into boxes and transfer to flowering positions in the autumn.

Prunus.—A large genus which includes the flowering peaches, Japanese cherries, and flowering almonds. All of them are best left to develop

REMOVAL OF SUCKERS—As illustrated, these must be sawn off into the root or pulled off the root with a sharp tug and never so removed that dormant buds are left.

naturally and are not responsive to pruning or cutting back in any way. A few sorts are over-planted in gardens and as street trees (by Park Superintendents), but anybody wishing to be a little out of the ordinary would do well to see the wide range of some of these lovely trees flowering in April and May in our botanic gardens and many of the large gardens now under the jurisdiction of the National Trust. The selection offered by nurserymen is often strictly along conventional lines. Lack of flower in some seasons can often be traced to bird damage.

Red-hot Poker.—*See* **Kniphofia.**

Rhododendron.—Greenhouse and hardy, evergreen and deciduous shrubs, including *Azalea.* With something like ten thousand different sorts, it is impossible to deal with individual requirements. General cultivation; an acidic soil is essential, with adequate moisture in summer. If growth is poor on established plants, mulch liberally with animal manure. Beginners should plant from the accepted list of hardy garden hybrids. Since the turn of the century widely planted and fine examples are to be found, for instance, in many gardens of the National Trust. *Prop.*—Seed and layering.

Romneya.—Since its introduction from California in about 1850 the plant has proved a fascination to gardeners, as sometimes it fails completely or does exceedingly well. It apears to require a light soil and a sheltered position, preferably against a sunny wall, and there is no point in trying to grow a romneya on a heavy, wet soil. Usually the annual stems die off in the winter and may be cut down at ground level in the early spring; if persistent the stems can be cut back to sound growth. The new growth is susceptible to slug damage, and appropriate steps must be taken (**T28**). *Prop.*—Seed or suckers taken off in the spring.

PRUNING ROSES—(A) A vigorous unpruned plant. (B) The same plant pruned for the production of exhibition blooms, (C) and pruned for garden decoration.

Rosa (Rose).—Undoubtedly the rose is the most popular of all garden flowers, and it may be found in a multitude of forms. The dwarf roses for bedding may be grown on most soils, but are best on a rich, heavy loam. Planting is done from early November onwards when soil conditions permit and the first pruning carried out in the following spring, when the extent of any winter damage can be seen. Opinions differ sharply on pruning; a sound, general rule is to do the work in March and—unless there are special circumstances—to prune on the light side. Thus, for Hybrid Teas and the like, reduce strong stems by about one-third of their length, medium ones by a half, and weak ones to within two or three buds of the main stem.

Whatever sorts of soil roses are grown in, feeding is important, but, of course, it is particularly so on poor ones. It is in soils of *low* fertility that diseases such as rust and black spot are most prevalent and, in some measure, persistence of the disease is due to bad cultivation and lack of treatment with fertilisers. Where black spot is established, spray with "Captan." For a manurial programme, an application of 2 parts of superphosphate and 1 part of sulphate of potash can be applied at 3 oz. per sq. yd. after pruning. Following this, a surface mulch of animal manure, compost, peat, or leaf-mould or a mixture of all of them is given about 2–3 in. thick. Subsequently, if growth is poor, a dressing of nitro-chalk can be made at 1 oz. per sq. yd. Some other manurial treatments, like the so-called "Foliar Feeding" and use of "special" (and often expensive) compounds, have little to commend them.

Where soil conditions are poor and disease prevalent, it is important to buy plants only from nurserymen who take special precautions to ensure that their customers have disease-free stock. Likewise, varieties of robust constitution are essential, and a selection list may include: *Hybrid Teas:* 'Christopher Stone' (crimson), 'Dame Edith Helen' (pink), 'Eden Rose' (magenta pink), 'Granmere Jenny' (yellow, rose-pink flush), 'Madam Henri Guillot' (salmon pink), 'Quebec' (yellow), and 'Tzigane' (bicolor: vermilion and yellow). *Floribundas:* 'Dainty Maid' (rose pink), 'Dusky Maiden' (dark red), 'Tantau's Surprise' (deep crimson), and 'Yellow Holstein' (yellow).

In most of the modern hybrids scent is almost absent. The true rose perfume is found only in the Old Fashion or shrub roses and, normally, these are planted in a mixed shrub border. For the richest perfume varieties like 'Mrs. John Laing' and 'Conrad F. Meyer' should be sought. *Prop.*—Nurserymen's plants are budded; many varieties are easily raised from cuttings taken in the autumn and struck in sandy soil out-of-doors.

Salvia.—Annuals, perennials, and tender shrubs. The most popular one is the scarlet sort used for bedding. It requires careful attention, and seed should be sown in February in a temperature of 60° Fahrenheit and seedlings put into single pots when large enough. Gradually the young plants are hardened off and finally planted out in rich soil in a sunny bed.

Saxifraga.—A large genus of plants suitable for the rock garden and valued for their bright flowers in the spring. The encrusted saxifrages are cushion-forming plants requiring sharp, surface drainage and an open position out of the direct

sun. The mossy saxifrages are mat-forming in growth and of easy culture. In time old clumps develop brown patches and then require splitting up and replanting in the spring.

Scabiosa.—The commonly grown perennial sort is *S. caucasica* and is invaluable as a cut flower. It is not at home on all soils, and only does really well in a deep, rich loam containing plenty of chalk. In addition, it must be grown in full sun and particular care taken against slugs. *Prop.*—Old plants divided in the spring and rooted pieces replanted in their flowering positions. A wide range of shades in white, blue, and purple can be had normally from sowing mixed seed in April.

Sedum.—The stonecrops make up a large group of hardy and tender plants, but comparatively few are of horticultural value. Notwithstanding, *Sedum spectabile* is to be found in most herbaceous borders, where its fine, flat heads of pink flowers are a feature for many weeks. It is beloved by bees and butterflies. *S. sieboldii* was introduced from Japan about 100 years ago and, although hardy, it is usually grown as a house plant. In the winter it can be stood out-of-doors, and every two or three years repotted in the spring; keep well watered during the summer and feed with liquid manure occasionally. *Prop.*—Division in the spring.

Sempervivum (House leek).—These hardy plants with succulent leaves often decorate the crevices of old walls and are regular features of trough or sink gardens. If given a light poor soil and a position in full sun a fascinating collection of house leeks can be built up. The species which gives the plant its common name can be established easily on a sunny roof by planting in a mixture of cow manure and clay during the spring. *Prop.*—Division in the spring.

Skimmia.—A hardy evergreen 2–3 ft. tall which is tolerant of shade and some degree of dryness. If growth is poor water with a liquid manure and mulch with peat or leaf mould. Some forms bear only male flowers and to ensure a good crop of berries plant an hermaphrodite like *S. foremanii*. *Prop.*—Layering in the autumn.

Snowdrop.—*See* **Galanthus.**

Snowflake.—*See* **Leucojum.**

Solanum capsicastrum (Winter Cherry).—A berrying plant with bright-red fruits which is often used for house decoration. To maintain the plant in a healthy condition it should be clear of draughts and fumes of gas fires and the foliage kept fresh and free of dust by vigorous syringing. If the stock is to be kept for more than one season water should be given only sparingly in the New Year, and in early March all the side shoots pruned back hard to within a bud or two of the main stems. As new growth develops, water can be given more freely and syringing started when the flowers first appear; liquid manure will prove beneficial when berries develop.

Spiraea.—Hardy deciduous shrubs for open borders; tolerant of poor soil conditions. The commonly grown one is *Spiraea bumalda* (syn. *japonica*). After flowering, a percentage of the old wood should be removed together with any weak growth, and development of new shoots encouraged by mulching with compost or animal manure. *Prop.*—Cuttings rooted in sandy soil under a hand light in summer; suckers thinned out in winter.

Stocks.—*See* **Mathiola.**

Sunflower.—*See* **Helianthus.**

Sweet William.—*See* **Dianthus.**

Symphoricarpos (Snowberry).—Often found existing in deep shade and in competition with roots of overhanging trees, presumably as a result of the generalisation that the shrub is a shade lover. Certainly a useful one in this respect, but it is responsive to good treatment. Given an average soil and if growth is thinned annually in the early spring, then *S. albus* 'Laevigatus' is well worth having. Its large white fruits are untouched by birds and hang well into the winter, and are thus beloved by the floral decorator. *Prop.*—Suckers removed in the winter.

Syringa (Lilac).—The botanical name of *Syringa* is often erroneously applied to the Mock Orange, correctly named *Philadelphus* (*q.v.*). A wide selection of first-class varieties are available in nurserymen's lists. To obtain heavy crops of flowers nip off all dead flower-heads as the blossom fades, but do *not* cut back into the old stem, as this will prevent flowering. At the same time any branches causing overcrowding can be removed. Annually feed with "National Growmore" at 2 oz. per sq. yd. and on poor soils mulch with any sort of manure or compost. *Prop.*—Layering in the autumn.

Tagetes (African and French Marigolds).—Half-hardy annuals of free-flowering habit and easiest culture. Best if fed generously with soot water or other nitrogenous manure during growing season. *See* **Annuals.**

Tropaeolum.—The common nasturtium and the flame flower (*T. speciosum*) belong to this genus. The former is easily grown from seed sown in May in a sunny position. The latter is a very difficult plant to grow outside the conditions which it demands. To be successful, this perennial climber must be planted in acid soil which is naturally damp and lightly shaded but yet where the new growth can reach full sun. Much disappointment often results from planting it in eastern England, for instance, after seeing it flourishing almost as a weed where the rainfall is high in Ireland and the west of Scotland.

In the genus will also be found the canary creeper, which can be used for screening purposes and will thrive in full sun or shade. Seed is sown in May in open ground and light supports supplied by way of pea sticks or strings; failure is normally due to nothing more than lack of moisture.

Tulipa (Tulip).—Thrives in a deep, rich loam, but will do well for one season in ordinary garden soil. When used for bedding, bulbs must be lifted after flowering, replanted in a trench, and thoroughly watered. Sometimes tulips may be left in the ground *if* conditions are favourable, and then the stock only needs lifting and replanting every three years. To check the incidence of tulip fire plant in late November or early December, covering the bulbs with 4–5 in. of soil and treat the ground with a fungicide like "Botrilex." Before doing so rake in a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per square yard. A small collection of wild tulips is being got together at Cambridge and grown there in the University Botanic Garden.

Viola.—This name embraces pansies, violas, and violets. Although the viola has not got the rich colours of the pansy (or its attractive markings), it has got a remarkably long season of flower, and for this reason it is invaluable as an edging plant or as ground cover for roses. *Prop.*—Both plants are easily raised from seed sown in a frame in the spring, pricked out, and then transferred to their flowering positions in late May. Alternatively, seed may be sown in July for planting out in October. Named varieties increased by cuttings in a frame in late summer.

Virginia creeper.—*See* **Parthenocissus.**

Wallflower.—*See* **Cheirianthus.**

Water Lily.—*See* **Nymphaea.**

Winter Sweet.—*See* **Chimonanthus.**

Wisteria.—One of the finest of all climbing plants for south or west walls or stout pergolas. Plants which do not flower, or only do so poorly, are probably seedlings and the true flowering habit cannot be induced; the only solution is to replace with a *grafted* plant of known flowering capacity from a reliable nurseryman. All young shoots not required for the extension of branches should be shortened to within 3 in. of the old stem in the

autumn. Wisterias growing over trees do not require pruning. *Prop.*—Layer shoots of current season's growth in the autumn.

Zinnia.—Half-hardy annual, ideally grown on moist, deep loam liberally enriched with well-decayed manure. Mulch with manure after planting and apply liquid fertiliser as buds appear; plants must not suffer from lack of water. *See* **Annuals.**

MAKING A LAWN

In almost every garden the most prominent feature is the lawn, and often a lot of work is put into making one without any great measure of success. Usually, the reason for failure may be found in faulty preparation of the soil or premature sowing, albeit the blame is often placed on bird damage or poor seed.

For anything like a reasonable turf, the site must be thoroughly dug and the content of organic matter increased by incorporating generous quantities of materials like peat, leaf-mould, compost, sewage sludge, and animal manure. A dressing of these ingredients can be applied in a layer 3–4 in. thick and buried in the bottom of the top spit of soil. As the ground is dug to incorporate the organic matter, roots of perennial weeds should be removed.

If the site is one on which water tends to lie or if the soil is heavy, then surface drainage should be sharpened by forking into the top 2 or 3 in. a liberal application of some coarse material such as builders' rubble, road grit, screened ashes, or coarse sand. In some cases this treatment will not be sufficient, and then the installation of land drains must be resorted to. This particular task is not as difficult as is sometimes imagined, but, before a start is made, it is always a good plan to discuss the matter with an experienced man.

After the initial work a fine tilth on the soil may be obtained by thoroughly raking and cross-raking and at the same time establishing a level surface. On this point, it should be remembered that good lawns can be made on undulating ground or on natural slopes, but the things to avoid are the shallow depressions where water will naturally tend to lie. Finally, ten to fourteen days before sowing the subsequent growth of grass can be encouraged by making an application of "National Growmore" at 2 oz. per sq. yd.

Sowing is best done in the late summer at a time when the soil is moist. For the purpose, a good mixture of seed should be obtained from a reliable seedsman, and it is worth paying a reasonable price for it, as, by and large, the coarsest and roughest grasses have the largest and heaviest seeds. Opinions differ on rates of sowing, but, with care and in a well-prepared soil, 1 oz. per sq. yd. is ample; heavier rates may give quicker results, but the density of seedlings in such cases often leads to the finer grasses being choked by the coarser ones.

After sowing, the ground should be lightly raked, but not rolled. At this stage the important point is to protect the seed bed from birds by the use of hazel sticks, strings of papers tied to stakes after they have been dipped in lime-wash, and strands of black cotton. Subsequently, annual weeds may appear in quantity; these are of no consequence, and they will be eliminated once the grass is cut regularly. Until a good turf is formed—usually about twelve months after sowing—it is not desirable (or probably necessary) to use hormone weed-killers.

Care of Established Lawns.

Most turf is never manured from year to year, and the soil may seriously lack plant foods. In the first place this can be corrected by making an application annually in the spring of "National Growmore" at 1 oz. per sq. yd. Subsequently, if growth is below par in the early part of the year an application of sulphate of ammonia can be made at the same rate. To avoid scorching or blackening of the foliage, each fertiliser can be mixed with equal parts of dry soil or sand as a carrier to ensure even distribution and, what is most important, each one should be applied only when the turf is wet and there is the prospect of rain to follow. Linked with this treatment, turf is always responsive to top dressings. A compost for the purpose can be made up with:

2 parts of loam;
1 part of sieved compost;
1 part of fine peat or leaf soil.

This may be used in the spring at 3–5 lb. per sq. yd. and if the soil is heavy 1–2 parts of gritty sand may be added.

With the introduction of new designs in motor mowers, most lawns are seriously overcut, and this has led to a sharp decline in the quality of the grass and the appearance of one or two pernicious weeds. It is appreciated that special turf, such as that found on a bowling green, may be shaved off to $\frac{1}{16}$ in., but if a utility lawn is cut below half to 1 in., then the quality of the grass will deteriorate. Of course, it is a good thing to occasionally cut the grass very short, but, conversely, if the blades of the mower are set as low as possible and left like it throughout the season nothing but harm can result. The reason for this hard fact is that when the turf is cut very close the grasses simply cannot develop and spread, and weeds will gradually establish themselves. Eventually the cultivator will be faced with the difficult problem of trying to deal with such plants as pearlwort, yarrow, and various mosses, all of which are resistant to hormones.

As for the vexed question of whether or not to remove the mowings, there is no doubt that the best turf is found where the mowings are collected up, although in very dry weather they can be left on the surface. If the clippings are not removed the surface of the turf tends to become choked with semi-decayed organic matter, and conditions are brought about which are inducive to the spread of moss.

Finally, it is worth noting that the finest turf is found on acidic—not alkaline—soils. For this reason, lime should not be applied as a general rule, for apart from helping the development of coarse grasses, it encourages the growth of clover. Of course, there are times when lime is necessary, but the occasions are rare and before it is used it is a good plan to test the soil by chemical means.

THE FRUIT GARDEN.

The guidance of an expert is probably more important in the growing of fruit than for most of the commoner vegetables and ornamentals. This is primarily because the majority of fruit trees and bushes are long-lived, and only in the case of strawberries can a change of site or variety be made easily and inexpensively.

Gardens which are low-lying are very prone to damage from spring frosts, and should not have too much space devoted to fruit, as returns may well prove unprofitable. Here, as with the selection of varieties, advice of a local expert is invaluable. Some varieties do better in certain localities and on certain soils than others, although personal preferences will naturally be met where possible. Varieties chosen should cover as long a season as is practicable so that the fruit can be used and enjoyed to the full.

Tree fruits are grown on a rootstock, and for apples and pears special dwarfing stocks make these a possibility for the small garden. It is therefore important to explain to the nurseryman what type of tree is required. As a general rule, however, the smaller gardens will gain by concentrating on currants, gooseberries, raspberries, and strawberries. Plums and cherries have no

dwarfing stocks, and should be included only where sufficient room is available.

Adequate preparation of the ground is important, and this, followed by good management, can result in worth-while crops from most soils, providing they are reasonably free of frost, well-drained, and sufficiently sunny.

Apples.—Can be grown on most soils. Manure should not be used when planting, except in sandy and chalky gardens. Obtain trees on dwarfing rootstocks, such as M.IX, M.VII, or MM.106. Always stake trees on M.IX, otherwise this practice is necessary only in exposed sites. The tie must be rigid, with a "cushion" between tree and stake to avoid chafing, and must be renewed annually to avoid constriction. Plant between late October and early March, preferably before Christmas if soil and weather allow. Make the hole large enough to spread the roots evenly; firm thoroughly while filling in and plant level with the nursery soil mark already on the tree. Mulch around each tree with manure or compost, mainly to avoid drying out, and supplement with watering during the summer when necessary.

In the first year any flowers produced are best pinched out to encourage root and shoot development. For walls or fences use oblique cordons or espaliers; these are also useful for flanking paths and lawns. Plant cordons 2½ ft. apart with 6 ft. between rows, and espaliers 12–15 ft. apart. For larger areas use bush trees 12–15 ft. apart.

Manuring for cropping trees should be varied according to growth. Generally apply 1 oz. sulphate of ammonia (or nitro chalk on acid soils) in early March, repeating this in early April if trees are growing in grass. Give ½ oz. sulphate of potash in February and add 3 oz. of superphosphate every third year. The above rates are per square yard, and a complete fertiliser can be used in lieu if preferred.

Young bush trees should have main shoots reduced by half in early years to produce strong branches. Thereafter prune side shoots to three to six buds. For weak growers prune harder, and for strong growers prune less. It is wiser to leave a strong tree unpruned than to prune it too severely, the latter merely encouraging even stronger growth. A few varieties (*e.g.*, 'Bramley's Seedling,' 'Worcester Pearmain') fruit at shoot tips, and here a proportion of side shoots should be left unpruned. Summer pruning is advisable on restricted trees, such as cordons; for details see pears. Very few varieties are self-fertile, and at least two sorts should be planted to ensure satisfactory crops. Good combinations are 'Cox's Orange Pippin' with 'Laxton's Fortune' and 'Winston' with the cooker 'Lord Derby.' Seek expert advice on pairings if in doubt.

Apricots.—These are often an unreliable fruit to grow, needing a well-drained, calcareous loam and a warm wall for success. Train the tree as a fan, and once established pinch unwanted side shoots to four leaves in summer. Thin fruits when young, these developing mainly on spurs on older wood. 'Moor Park' and 'Hemskirk' are good varieties.

Blackberries.—Allow plenty of room and train against fences or wires. Autumn planting is preferable, using good, well-manured soil and cutting back the cane to 9 in. from the ground. Mulch with manure each spring, water freely in drought, and cut out old canes as soon as they have fruited. Good varieties are 'Himalaya,' 'Merton Thornless,' and the parsley-leaved blackberry. Increase by tip layering.

Cherries.—Sweet cherries are unsuited to most gardens. The trees become too large, and *must* be planted in selected pairs to fruit satisfactorily, as all varieties are self-sterile. Large wall spaces are ideal for fan trees, as the fruit can then be protected from birds by the use of nets. Pinch side shoots on fans to four leaves in July; further pruning details being as for plums. Expert advice is essential to ensure that suitable varieties are grown together, the factors involved being complicated. 'Early Rivers' with 'Bigarreau Schrecken' and 'Merton Heart' with 'Waterloo' are good combinations.

For the small garden the dwarf-growing, acid 'Morello' cherry is more useful, being infinitely superior for preserves as well as self-fertile. It also succeeds on a north wall, but unlike sweet varieties, fruits *only* on one-year-old wood.

Currants, Black.—These are perhaps the most valuable of all hardy fruits, and bushes will give up to 10 lb. and more of currants with correct treatment. Plant from November to February, preferably autumn, at 5 ft. square on clean, heavily manured ground. Then cut all shoots to one bud above soil level. Mulch each spring with well-rotted manure and supplement with fertilisers if necessary. The mulch is essential as much for keeping the soil moist as for a general feed.

On established bushes prune preferably after fruiting or in winter, retaining strong young wood and cutting out older shoots, where possible from ground level. If necessary, alternate bushes can be cut down completely every other year to maintain vigour, as the bulk of the crop is always borne on young wood. Increase by 8-in. cuttings of one-year-old wood taken in late September from healthy bushes. Remove lower leaves and insert firmly with one bud above ground. Good varieties: 'Boskoop Giant,' 'Wellington XXX,' 'Baldwin.'

Currants, Red and White.—One or two well-grown bushes are usually sufficient for the average household. Plant between November and March at a minimum of 5 ft. square on well-manured ground and mulch each spring. Supplement with fertilisers if necessary, potash being particularly important in the form of sulphate of potash at 1 oz. per sq. yd. in February. Can be grown as cordons or fans against walls or fences, on which the pinching of young side shoots to four leaves in mid-June is essential. Winter pruning of all types simply involves cutting side shoots to one bud and tip pruning branch leaders. Propagate by 12-in. cuttings of young shoots in late September inserted to half their length with all buds removed except the top four. This enables the bush to be grown on a "leg." A permanent framework of branches is then developed, as, in contrast to the black currant, fruit is borne on spurs on the old wood. Good varieties: 'Laxton's No. 1,' 'Red Lake,' 'White Grape.'

Damson.—*See* Plums.

Figs.—A warm south wall is usually essential, 'Brown Turkey' being one of the few reliable outdoor varieties. Plant in a brick or concrete trough (with drainage holes) about 2½ ft. wide, 5 ft. long, and 2½ ft. deep so that the root run is restricted. This will curb excessive growth (which otherwise is difficult to control) and encourage fruiting. Plant in March for preference, to avoid frost injury to young shoots, and then train fan-wise. A rich soil is not essential. Figs visible as such in the autumn will never overwinter, and should be rubbed out. Those the size of a pea and less at the tips of short, well-ripened shoots, on the other hand, are the potential crop for the following year, and should be covered in severe weather to avoid frost damage. To encourage the formation of these embryo fruits pinch young shoots back to the fifth leaf in late August. Winter prune in March, removing any wood that is frosted, overcrowded, or worn out; growths should be spaced at about 1 ft. Apply a spring mulch and water freely when required to avoid premature fruit drop.

Gooseberries.—Need conditions and spacing very similar to red currants, but with rather more moisture to ensure ample new wood, as this bears fruit as well as the older wood. Apply sulphate of ammonia and sulphate of potash annually in late February at up to 1 oz. per sq. yd. of each in addition to mulching. Can also be grown as cordons, etc., as for red currants. Pruning is also similar, though not quite so severe, as the young wood is productive of fruit. Cuttings are more difficult to root, and for best results should

be taken in mid-September, again as for red currants. Good varieties: 'Lancer,' 'Leveller,' 'Whinham's Industry.'

Grapes.—Outdoor vines should be grown against a warm south- or south-west-facing wall. With good cultivation, the grapes should then ripen successfully providing suitable varieties are chosen. In preparing the site ensure that it is well drained and break up the soil to a depth of about 2 ft. Add bone meal to the top few inches at 4 oz. per sq. yd. and incorporate mortar rubble, particularly on the heavier soils. Do not dig in any manure except on poor, light soils, but always apply some as a mulch after planting, repeating this every spring. On poor, hungry soils the importation of some fibrous loam is advisable where possible.

Plant in November or, failing this, before early March, with the stem about 6–9 in. away from the wall. Firm well and then wait a further two months before tying to any wires or stakes, in case of soil sinkage. Cut the vine back in winter to well-ripened wood and to just above a bud. The training of subsequent growth will then depend on the space available, single and double cordons being the most convenient. Unwanted shoots should be pinched at about 2 ft. in summer and leading shoots carefully tied in to wire or bamboo supports. The following winter (December) prune leading shoots back to well-ripened wood so as to leave 3–4 ft. of new growth. Then cut all laterals hard back to one bud. In spring reduce young side shoots to one at each bud, stop laterals at about 12 in., and pinch any sub-laterals that may develop to the first leaf. Do not allow any crop to develop, except perhaps one bunch if growth is adequate; others should be pinched off. As fruit develops, thinning should be done as required. Winter prune as before, and then in the third summer four or five bunches of grapes can be allowed if the vine is healthy, the crop then increasing annually. Shoots carrying bunches should be pinched to two leaves beyond the bunch. Winter pruning is repeated each year as already described. Sour top-soil should be carefully removed when necessary and replaced with good loam while the vine is dormant. Good varieties: 'Black Hamburgh' and 'Foster's Seedling.'

Loganberries.—A very popular hybrid berry which should be treated as for blackberries. A thornless form is now available. Suitable for a north wall.

Medlars.—A tree of spreading habit, the peculiar fruits of which are best used for jelly before they are fully ripened. Most soils are suitable, and no pruning is needed except to keep in shape.

Nectarines.—A fruit very closely allied to the peach but with a richer flavour and needing rather more warmth. The skin is smooth, as distinct from the hairiness of the peach. For full details see **Peach.**

Nuts.—The most important kinds grown are cobnuts, the closely related filberts, and walnuts, but none of these is cultivated to any great extent. The two former kinds flower very early in February, and are therefore predisposed to frost damage; similarly, the young shoots of walnuts are easily injured by spring frosts, and all are therefore inadvisable for frosty areas.

Cobnuts and filberts.—Highly developed forms of the ordinary hazel nut. The nut of a cob is only partially covered by the husk, whereas a filbert is completely enclosed by it, this being the essential difference between the two. Will grow on most soils, including the poorer ones, and spacing should be about 15 ft., choosing sites sheltered from the colder winds. Plant during the autumn. Prune established bushes in March, cutting back shoots that have borne nuts to two or three buds; strong young shoots are cut back to a catkin near their base, and the weaker ones are left untouched. In August any strong new side growths are "brutted"—that is, broken off—and left hanging until the March pruning. Gather the nuts as they fall and allow to dry. Then store in jars for Christmas use, packing salt and coconut fibre between each layer of nuts.

Walnuts.—Special, grafted varieties are now available which produce early crops compared with the unreliable seedling trees that used to be planted. Plant between October and March and water well in spring and summer. Do not prune, as walnuts bleed badly. Gather nuts in mid-July for pickling. For storing allow to drop naturally and remove outer husk immediately, scrubbing the shell clean and then drying thoroughly. The shells can be bleached if necessary before storing the nuts as for cobs above.

Peaches.—This fruit along with its close ally, the nectarine, is best grown against a warm south or south-west wall, but two varieties of peach, 'Peregrine' and more particularly 'Rochester,' will succeed as bushes in the open in southern England. The fan-trained peach is one of the most difficult trees to keep in order, as sufficient new shoots must be retained annually to replace old wood. This is essential, as it is only the previous year's shoots which bear fruit. Badly placed shoots are rubbed out when only an inch long, and the principle is to allow one young replacement shoot to develop near the base of each fruiting shoot, pruning back to the former and tying it in as soon as all fruit has been picked. Other shoots may be used to extend the fan where space allows or to replace any branches or parts of them which may have become worn out. Other unwanted shoots are bound to arise during each summer, and these are either removed immediately or pinched to three leaves and then removed when pruning in late summer. Those shoots retained are spaced at about 4 in. apart.

Most peaches are self-fertile, but hand-pollinating on sunny days can improve the set. Excessive feeding should be avoided, varying this according to each tree's performance, but as a general rule a surface mulch of well-rotted manure or compost should always be given each spring, together with sulphate of potash at ½ oz. per sq. yd. Prick over and rake off top-soil and replace with good loam every few years. Never allow the sub-soil to dry out—this can quickly occur against warm walls—and water thoroughly when doing so to ensure an even distribution of moisture. On the other hand, drainage must be satisfactory to avoid waterlogging.

There are numerous other essential operations in the growing of trained peach trees (for example, fruit thinning), and it is impossible to deal with these adequately in brief notes. Would-be growers should therefore seek expert advice and obtain literature dealing specifically with the crop rather than risk disappointment. Good varieties for outside wall training include: *Peaches:* 'Peregrine,' 'Bellegarde.' *Nectarines:* 'Early Rivers,' 'Lord Napier.'

Pears.—The requirements for pears are similar to those for apples, but the necessity for adequate summer and autumn warmth rules out many varieties for northern areas. In these less-favoured localities enquire which varieites do succeed, and where possible make use of a warm, south-facing wall. Protection from wind is very important, particularly from the cold easterlies of spring. Many soil types grow pears satisfactorily, providing drainage is good and the trees are looked after. Plant as for apples. Fertiliser requirements are also similar once cropping commences, except that pears may require a little more nitrogen.

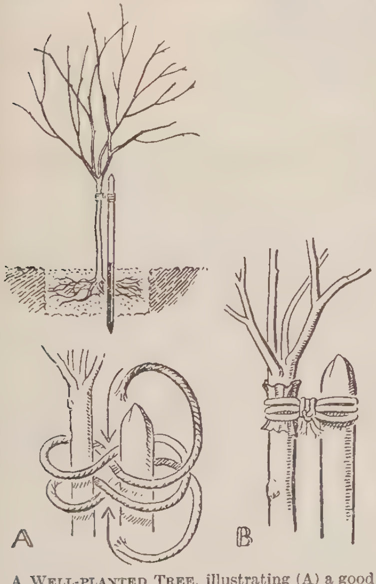
Pruning (winter) is comparatively simple, the spur pruning given for apples suiting all except a very few pears. Initial shaping is essential, cutting the stronger shoots selected to form branches by about half their length and keeping the centre of the tree open. For cordons and other restricted forms of tree, to which pears lend themselves particularly well, summer pruning is advisable. This involves shortening all young shoots more than 10 in. in length to about 5 in. from the base. Do this when the base of such shoots is hardening and turning brown in colour, usually late July–early August. Pruned shoots may then be further reduced in winter. Such summer treatment may also be given to trained apple trees with advantage during August.

Only a few pears are self-fertile and 'Con-

ference' is the most reliable if only one tree can be planted. Good pollinating pairings include 'Laxton's Superb' with 'Doyenné du Comice' and 'Conference' with 'Williams' Bon Chrétien.' Early varieties should be picked a little before ripening and used quickly.

Plums.—This general term includes gages and damsons. Numerous varieties are easy to grow but are unsuited to small gardens because of the amount of space required. Unlike apples and pears, there are no dwarfing rootstocks, and a minimum spacing of 14 ft. should be allowed for, growing the trees as half standards, or fan-trained against a south or west wall. Flowering is during April, and frost damage can be serious in some seasons. Plant preferably in the autumn, and by early March at the latest, using no manure unless soil is distinctly poor. Young trees should be staked during their early years, and must not be allowed to rub against the support.

Pruning should be reduced to a minimum, as the spores of silver leaf disease gain entry through wounds such as pruning cuts and stake rubs. Shorten branch leaders on young trees just as buds are bursting, but on older trees prune only when branches become overcrowded. Do this between June and August, when the risk of silver leaf is at a minimum. Cut cleanly and coat the wounds thoroughly with a bituminous paint; treat broken branches similarly immediately they are noticed. Trees fruiting heavily should have the branches supported and the fruit thinned in late June. Side shoots on fans must be cut to four to five leaves in late June and reduced still further following picking if necessary. Feed cropping trees regularly to encourage new growth, using well-rotted manure or sulphate of ammonia at 1 oz. per sq. yd. in early spring. Some varieties are self-fertile including 'Victoria,' 'Oullin's Golden Gage,' and 'Merryweather Damson.'



A Well-planted Tree, illustrating (A) a good method of tying and (B) sapling firmly secured with sacking around the trunk and held with stout cord.

Raspberries.—These are an ideal fruit for the small garden, but because of virus disease always buy certified canes from a fruit nursery. Plant between November and March on clean, well-manured ground, allowing 18 in. between canes and 6 ft. between rows. After planting prune each cane back to 12 in. Do not attempt to crop them in their first year, or the production of young canes for the following year's fruit will suffer.

A semi-shaded position will answer, but full sun is preferable for quality fruit. New canes should be looped with string to a post-and-wire fence and later tied individually to each wire when fully hardened. Space them at about 4 in. and remove any weak or diseased canes at ground level. In late February cut each cane to just above the top wire, which is usually 5–6 ft. high. This removes any damaged tips and may encourage fruiting over a longer length of cane. In the second summer a fair crop should result, and netting against birds is essential. Regular watering is imperative in dry weather, and spring and summer mulches of well-rotted manure or compost should always be applied. Supplement this in March with nitrogen and potash (fertilisers) if required, this depending on how well the ground was manured before planting. After fruiting cut out all old canes and tie in the new ones as already described. 'Malling Promise' and 'Lloyd George' are good varieties.

For autumn-fruiting varieties prune all canes to the ground in late February and tie in the best during the summer for cropping in September–October. 'September' is a good variety, and 'Lloyd George' can also be used.

Strawberries.—This is the one fruit that should be included in the vegetable garden. Fresh ground can then be used regularly for establishing new beds. Plants more than two years old are seldom profitable, and the best fruit is always picked from healthy one-year-olds planted the previous August or September. Runners put in later than early October should be deblossomed the following spring, the reward being a much heavier crop in the second year. This wastes ground, however, and early planting is preferable on all counts. Prepare the ground well in advance of planting and dig in plenty of well-rotted manure or compost or both, as this is the key to success.

Because of virus diseases order certified plants from a fruit nursery and burn any unhealthy ones in old beds before planting. Insert firmly with the base of the crown of each plant just at soil level and refirm after winter frosts; space at 20 in. in rows and 2 ft. 6 in. between rows (3 ft. if possible). A mulch of rotted manure or compost is beneficial each autumn, and if this is lacking apply sulphate of potash at 1 oz. per sq. yd. instead. Bonemeal is also advisable in spring and again in July, but quick-acting *nitrogenous* fertilisers should normally be avoided.

During flowering cover the plants where possible to guard against frost damage reducing the crop. Keep the ground weed-free and remove runners regularly; a few plants should always be grown away from the main bed, deblossomed and kept purely for runner production, as this then helps to reduce the spread of virus. Ruthlessly burn any plant that remains stunted, including its runners, as this is usually a symptom of virus disease. When the young fruits are just forming spread clean straw underneath them to avoid splashing from the soil; it is a mistake to do this too early, as it increases the risk of frost damage. Net the fruit against birds and remove any rotting specimens when picking.

After fruiting remove and burn all old foliage, weeds, and straw, and feed as already described. Plant a percentage of new, vigorous runners each year on fresh ground, at the same time burning the old ones they are replacing. Good varieties include 'Royal Sovereign,' 'Cambridge Favourite,' and 'Talisman.'

Alpine strawberries require similar treatment, preferably with a semi-shaded position, and should be raised from seed. Perpetual fruiting types continue fruiting on and off well into the autumn, and should be treated as for ordinary varieties. In all cases cloches can be used from late February onwards to obtain early fruit.

THE VEGETABLE GARDEN.

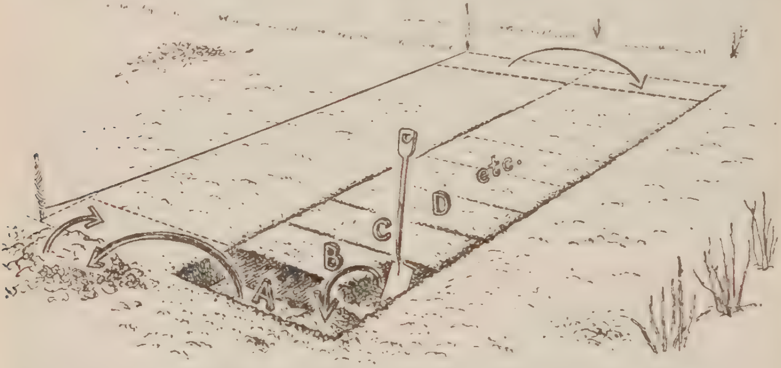
The vegetable garden is, or should be, an integral part of home economy nowadays. Home-grown vegetables, although requiring considerable labour, are cheaper and fresher than most shop supplies. The ideal site is in an open, sunny position sheltered from cold winds with the soil a deep, rich loam well supplied with humus; quite obviously very few gardens have the ideal site, and we have to do the best we can with the ground available. In laying out the vegetable plot, ease of working should be considered; the lines of vegetables should go from north to south, and paths should be wide enough for a barrow to pass. The vegetable lines should not be too long, or the soil will be trodden down too much.

Each individual will have to decide the size of his plot according to the amount and types of vegetables required, and the land available. Shelter from a hedge or wall is desirable, and a plot about 90 ft. by 30 ft. can be made to produce a succession of vegetables to feed an average family over the year. Land preparation is important; on a new site the weeds should be cut down and removed, but any turf can be left and dug in. The land should be dug two spits deep (" double digging ") in winter, and for this the plot is divided into two longitudinally and a trench 2 ft. wide and 10 in. deep is dug out at one end, as shown on the accompanying diagram. The sub-soil below the trench is then broken up and manure or compost incorporated (or turf if grassland is being dug). The next strip is then dealt with in a similar manner, and this continues down the plot until the last trench, which is then filled with the loose soil from the first trench.

Clay soils which are sticky are much improved by humus and constant working, but should not be dug in wet weather. Sandy soils also require plenty of humus to conserve moisture, but are less fertile, though often warmer and earlier. For the majority of vegetables a slightly acid soil is best, and a dressing of lime is only desirable if the soil is too acid. Double digging is not necessary each year, and single digging, carried out in a similar manner without breaking up the second spit, or a light forking over is sufficient for some crops, provided the ground has been well cultivated previously.

The lay-out with vegetables must be designed to provide a succession through the year and to utilise the full capacity of the ground by catch crops and a suitable succession. The land can be divided into four plots; one is used for the more or less permanent crops, such as asparagus, rhubarb, and globe artichokes, and the other three will provide a rotation. This is used to stop any group of vegetables being grown on the same land more than once in every three years, so preventing the carry-over of some pests and diseases and providing for a full use of the manures in the soil, as different groups of vegetables need more of some nutrients than others. It also allows the clearance of one section to enable winter digging and manuring to be carried out. On this freshly manured plot peas, beans, onions, leeks, and lettuces, all revelling in rich ground, should be grown. The next plot, manured for the *previous* crop, can be used for root crops—early potatoes, carrots, parsnip, and beet. A light dressing of artificial fertiliser such as " National Growmore " should be applied before sowing. On the third plot the green vegetables should be grown; a dressing of fertilisers is desirable, and lime should also be applied.

In the following season the root crops can be grown on the plot which was manured the previous year, and the brassicas grown on the land vacated by the root crops. The plot on which the brassicas were growing is double dug and manured ready for the peas, beans, and onions. A system of this type proves very satisfactory, but numerous variations can be devised, and it is really a matter for the gardener to decide his best method. The growing of maincrop potatoes will complicate the system, as a large area is usually required. They are better grown separately in another part of the vegetable garden.



DOUBLE DIGGING—A sound cultural practice. A trench 2 ft. wide and the depth of a spade is taken out at A and placed as shown. The bottom of trench A is then forked up and filled in with soil from B and the process repeated with C and D, etc. In double digging the sub-soil is *always* left on the bottom and never brought to the surface.

Usually it is wise to have a small piece of ground available for a nursery bed. This should be of good, fine soil in which seeds can be sown to supply the main plot. In all cases seed should be sown very thinly to prevent the necessity for much pricking out, and a slug-killer is often a wise precaution to use before sowing. Sowing dates, as given, are mainly for growers in the South. In the North sowing dates in spring will be generally two weeks or more later and autumn operations the same amount earlier. Any gardener must adjust his work to suit local conditions of soil and climate, and this knowledge is only gained by experience of the particular area.

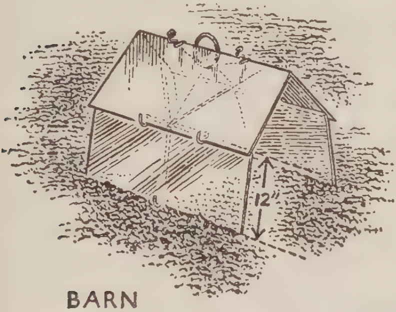
General cleanliness in the vegetable garden is at all times desirable; weeds and rubbish only harbour pests and diseases, and the hoe should be busy whenever possible. Waste material can be utilised in that essential of the modern garden—the compost heap. *See* **Manures and Fertilisers** for description.

Frames and Cloches.—The gardener is able to extend the season of many crops by protecting them under frames and cloches; this is particularly useful where spring or early autumn frosts are prevalent. The use of frames is limited, as they are in a fixed position, but nevertheless they are very useful for obtaining out-of-season salad crops, especially if they are heated by electricity or a hot bed.

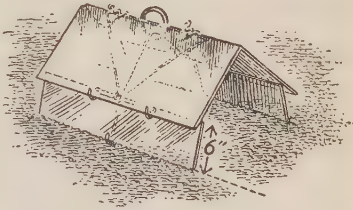
Cloches have the advantage of mobility and can be used on a number of crops in succession. Essentially, each is a number of pieces of glass in a tent or barn shape held together by wire. Pattern, size, and height vary according to the crop to be covered and the manufacturer's design. A good cloche should be of simple design, rigid and capable of standing up to ordinary winds, easily transported, and well ventilated.

The low barn cloche is probably the most economical type. This is 23 in. wide and 13 in. high when erected, and will allow two rows of lettuce to be grown, with an intercrop of another vegetable. The large barn or barn cloche of similar design, but with 12-in. side is 19 in. high in the centre, enabling taller crops, *e.g.*, peas and dwarf beans, to be grown on, almost to maturity.

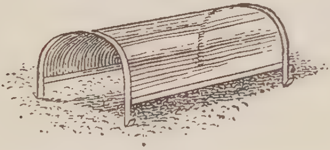
Dwarf varieties should be used for growing under cloches, although methods of raising the cloches another foot or so have been devised and are on the market, which allow the use of taller growing varieties. Many different vegetables can be helped to some extent in the early stages, besides those crops which can be grown entirely under cloches; the grower must decide what crops he needs and fit a rotation to cover as many crops as possible with the cloches available. This is mainly a matter of experience, but books on the subject will suggest many variations that can be tried. Intercropping with quick-maturing crops can also be practised. As instances, radish or mustard and cress can be cropped between two rows of lettuce, or a row of cos lettuce can be grown between two rows of cabbage lettuce.



BARN



LOW BARN



PLASTIC

TYPES OF CLOCHES—The most popular is the barn cloche; with 12-in. sides it will cover strawberries and peas and beans in their early stages. The low barn will accommodate three rows of lettuce in winter and cucumbers in the summer. Plastic cloches are growing in popularity, especially those patterns using toughened plastic, and have some decided advantages over glass ones.

The tomato cloche has sides 24 in. square and a basal width of 26 in. Many others of various shapes and sizes are offered; the amateur should buy to suit his own requirements. Other materials have been tried instead of glass with varying success. Plastic cloches are on the market, but their lightness entails very safe anchoring, and at the moment glass still seems to be the best material in most instances.

Gardening under cloches obviously is a subject too large to be dealt with in a few sentences, and the reader would be well advised to refer to one of the books mentioned in the bibliography for fuller information. A few of the main points are mentioned here and also under the individual crops.

Cloche cultivation is an intensive method of production, and this means that the land must be well cultivated and manured to ensure good-quality crops at all times. About ten days before crops are sown or planted the cloches should be put in the position where they are to be used, to warm the soil. The crop is sometimes sown a month before the normal date, and this prewarming ensures that the soil can be cultivated to a good tilth, as well as giving the plants a good start. Watering is a problem that often bothers the amateur. Provided the soil is well watered at sowing time, there should be no need to decloche to water. Rain seeping under the cloches and a spray directed over them occasionally will provide enough for the crop in normal weather; on dry, sandy soils it may be necessary to spray over the cloches more often. A mulch of compost is also very useful to help retain water.

It must be remembered that the glass of cloches will need cleaning from time to time; the crop still needs the maximum light available, although shading of certain crops may be necessary in hot sun.

Artichokes.—Two different plants are grown as artichokes. One, the Jerusalem artichoke (*Helianthus tuberosus*), is related to the sunflower and is grown for its tuberous roots, which are second in food value only to the potato. It will grow in poor soil, but amply repays good cultivation, and may be placed at the more exposed end of the vegetable plot as a windbreak and screen. Tubers should be planted during February or March, on well-manured ground in drills 4–6 in. deep, and 2 ft. 6 in. apart, with 15 in. between the tubers. Hoe frequently during the summer and cut the stalks down in early winter. The tubers may then be lifted and stored, or better dug as required, reserving a number for replanting the following February.

The other type, the globe artichoke (*Cynara scolymus*), is often grown as an ornamental plant, but is esteemed as a vegetable for its young, fleshy flower-heads, which must be cut before the scales begin to open, after which they become hard and unpalatable. A deep, rich, well-manured soil is required, and after planting in early spring in rows 4 ft. apart, with 2 ft. between the plants, a compost or manure mulch is beneficial. A good crop may be expected for five or six years provided an annual dressing of manure is applied. After this time they should be replaced by young suckers,

planted in a fresh position. A covering of straw or bracken on the crowns is advisable during winter.

Asparagus.—This will grow on most types of soil provided that drainage is good and that plenty of organic matter is available. The site for the asparagus bed should be double dug in the autumn prior to planting, and a generous dressing of about half a barrow load of manure per square yard incorporated. Crowns up to three years old may be bought, but it is found that one-year-old crowns give the best results. Plants may be obtained cheaply by sowing seed in late March in drills 1½ in. deep and 18 in. apart and thinning the seedlings to 4 in. apart. It is thought that male plants produce more stalks of better quality than female plants, but at present no supplies of male crowns alone are available.

Planting may be on the single-row system or the wide-bed system. In the single-row system crowns are planted 18 in. apart in rows 4½ ft. apart; the wide-bed system consists of 5-ft. beds, with three rows of crowns 15 in. apart each way, and 2 ft. between each bed. Planting is best done during April and the plants are placed in a trench 8 in. deep and 1 ft. wide, with a slight ridge at the base, and covered with 3 in. of soil. The remaining soil is worked in during the summer. The roots should never be allowed to dry out.

The following March 2 oz. per sq. yd. of sulphate of ammonia should be applied; in subsequent years 3 oz. per sq. yd. of "National Growmore" applied at the same time, followed by 2 oz. per sq. yd. of sulphate of ammonia in June, after cutting, can be used. Salt, as a fertiliser, is not recommended nowadays. An annual dressing of manure or compost in November is desirable.

No cutting should be done for the first two years after planting and only a light cut taken in the third year. After this a six-to-eight-week season beginning in early May is usual. The spears should be cut when about 4 in. above soil level and severed about 2 or 3 in. below the soil, giving an overall length of 6–7 in. The fronds should be cut in October before the seeds drop, but not during the summer, as the plant is weakened. Weeds should be kept down, and in the autumn the plant may be earthed up.

Varieties: 'Connover's Colossal' and 'Kidner's Pedigree.'

Beans. Three types are commonly grown.

Broad Beans are the hardiest and can, in warm gardens, be sown during autumn to obtain an early crop. Little is gained by this as a rule, and sowing in well-manured ground in February, when the soil is frost free, with successional sowings during March and April, is generally better in most gardens. The soil is broken down, finely raked, and the seed sown 9 in. apart in drills 3 in. deep, with 18 in. between each row. If double rows are sown 10 in. should be left between the rows, and 2 ft. between each pair of rows. Staking may be necessary. Plants from sowings under glass or under cloches in January may be used to obtain an earlier crop; the cloches should be removed in March and a further crop sown, and recloched.

Black aphis was a serious pest, but is now easily checked by pinching out the young tips and applying malathion or lindane as soon as any are seen. The pods may be used before the beans are fully developed and sliced as are runner beans, but normally they are picked when the beans are well formed but not tough.

Varieties: 'Aquadulce' and 'Seville Longpod.'

Dwarf Beans (which include French, Kidney, and Haricot Beans) may be either used as young pods in a similar manner to runner beans or ripened in the pod for winter use. A rich well-manured soil gives the best results, and seeds sown during the first week in May, 2 in. deep and 6 in. apart, in drills 18 in. apart, may be followed by a second sowing at the end of May. The young plants should be thinned out to 1 ft. apart and small twigs used to stake them. If sown earlier, frost damage may occur. Seeds may also be sown in the greenhouse and the seedlings transplanted, or sown under cloches in the last week in March, provided the soil has been prewarmed.

The plants, as long as the pods are picked over frequently, will continue to bear until the frosts; a little liquid manure will be beneficial during the summer. A late sowing in July, cloched in September, will continue the season into the autumn.

If required for winter use (Haricot varieties) certain plants should be left unpicked and the pods allowed to ripen on the plants. They should not be picked green; if unripe when frosts come, the plants should be pulled up and dried in a shed.

Varieties: 'The Prince' (Cloche), 'Masterpiece,' and 'Comtesse de Chambord' (Haricot).

Runner Beans are the most popular type, and can be grown in two ways: either without stakes, in which case the tips of main and side shoots are regularly pinched out to make a bushy, dwarf plant, a method often used by farmers, or staked, with cross poles, allowing the plants to climb to the tops of the poles before pinching. Seed is sown from early May (mid-April under cloches) until late June, depending on the danger of frost, usually in a double row with drills 15 in. apart, and with seeds 3 in. deep and 6 in. apart in the rows, alternate plants being removed later.

Staking should be done as soon as the first pair of leaves unfolds, and a surface mulch is then applied. If the beans are to be dwarfed the rows should be about 18 in. or 2 ft. apart, and pinching may be required about once a week. A good, well-manured soil is essential, and plenty of moisture is required. The flowers may fail to set in dry weather, and an evening spray of water is helpful in preventing this "running off." Harvesting should be carried out regularly while the pods are young, before the seeds swell; older pods are stringy and seldom worth eating.

Varieties: 'Achievement,' 'Goliath,' and 'Princeps.'

Beetroot.—From mid-April onwards varieties of beet may be sown on soil that has not recently been manured but is in good heart; on freshly manured soils coarse, forked roots subject to cracking occur. If in poor condition a light dressing of a complete fertiliser should be given before sowing. Sow in drills 1 in. deep and 12 in. apart and make a first thinning to 4 in. apart when the first rough leaf appears, and a second later, leaving 9 in. between the plants. Transplanting is inadvisable. Early roots for summer pulling may be obtained from a sowing of a Globe type in mid-April, and the main sowing should be made during May or early June for the winter supply. A sowing under cloches in late February will provide roots for pulling in late May.

On a heavy soil the oval-rooted types are best, but on a lighter soil the long-rooted types may be used. A sowing in late July of the Globe type will provide beet for use at the end of winter. Salad beet from early sowings may be pulled as required; the main crop should be allowed to mature and is lifted in October before the roots become woody and tough. Any damaged roots should not be stored. Twist off the tops just above the roots, shake the soil from the roots, and store in boxes of sand or peat in a frost-free shed. If clamped outside, straw and a thick layer of soil should be used; if frost reaches them they are spoilt.

Varieties: globe—'Early Model', 'Red Globe' and 'Crimson Globe'; oval—'Cobham Early'; long—'Cheltenham Greentop.'

Sugar beet is similar but is white, not red-fleshed, and is mainly a farm crop; if desired it may be grown in a similar manner. Care should be taken in hoeing all beet crops to avoid damage to the small surface roots which feed the swollen rootstock.

Borecole.—*See* **Kale.**

Brassica.—A generic name of vegetables usually known to gardeners as "greens." This group includes brussels sprouts, cabbages, cauliflowers, kale, turnips, kohl-rabi, broccoli, and couve tronchuda. As they are all related, similar soil and cultural treatment is needed, and many pests

and diseases are common to them. Each is dealt with under a separate heading.

Broccoli.—*See* Cauliflower.

Brussels Sprouts.—Young plants from seed sown thinly in a nursery seed bed during mid-March can be transplanted during May or June. The soil should be firm, well drained, in good heart, and contain adequate lime, some manure preferably having been dug in during the winter; a supplementary dressing of 2 oz. superphosphate and 1 oz. of sulphate of potash per square yard is given before planting. The young plants should be set out 3 ft. apart both ways, planted firmly, and watered in thoroughly. Regular hoeing is necessary, and about a month after planting a little soil should be drawn round the stems.

If growth seems weak a top dressing of nitro-chalk should be given and this repeated in early September. As the lower leaves yellow, cut them off and gather the sprouts as they mature, picking from the bottom of the stem. Where space is available a succession of sowings from March to June can be made to lengthen the cropping period.

Club root, the worst disease of brassicas, is kept in check by only using well-limed, well-drained soil, and dipping the roots in 4% calomel before planting, and cabbage root fly, a frequent insect pest, by using dieldrin.

Varieties: early—'Cambridge No. 1' and 'Masterman'; mid-season—'Evesham Special'; late—'Feltham Longstanding.'

Cabbage.—Sowings in March and April for summer use, in May or June for winter use, and in late July or August for spring use will give a succession of cabbages all the year round. Seed is sown thinly in a nursery bed of well-firmed, limed soil, clear of weeds, in drills ¾ in. deep and 6 in. apart, and the seedlings are dusted with D.D.T. to check flea beetle attack (prevalent with all brassica seedlings). All cabbages are gross feeders, and a well-drained soil in good heart, with adequate lime, is required.

"Spring cabbage" should be sown during late July (north) and August (south). If sown too early the plants may "bolt" without making a heart. The young plants are set out in mid-September 18 in. apart and with 18 in. between the rows if for hearting, or 9 in. apart with 18 in. between the rows, in which case the alternate plants are cut for "spring greens." On a heavy soil ridging along the rows of plants keeps the soil round the roots drained and helps to prevent loosening by frosts. In cold districts cloches may be used with advantage to help plants through the winter. In early March a dressing of 1 oz. per sq. yd. of sulphate of ammonia or nitro-chalk is a good stimulant.

Seed of "summer" and "autumn cabbage" is sown in March and April and planted during late May and June, 18 in. to 2 ft. each way between the plants, depending on the variety. The plants should be thoroughly watered, both before and after transplanting. A top dressing of 1 oz. per sq. yd. nitro-chalk may be given if required.

"Winter cabbage," maturing from October to February from sowings during May and early June, are set out 2 ft. apart each way in July or early August, usually on ground which has been cropped with early potatoes or peas. No nitrogen fertiliser should be given late in the season, as soft growth, liable to frost damage, is encouraged. A balanced fertiliser, such as "National Growmore," may be used if needed. When the stalks of cabbage are left standing over winter a common practice is to cut across the tops to obtain bunches of leaves, for use as greens during early spring.

"Savoy cabbages" mature during winter and early spring from seed sown in May. Seedlings are transplanted in late July and early August on to land manured for the previous crop, to which a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per square yard has been given. The young plants should be set out 2 ft. apart each way; they are exceptionally hardy, and should be grown in every garden in case of a hard winter.

Varieties: spring—'Early April' and 'Wheeler's Imperial'; summer—'Golden Acre' and 'Primo'; winter—'January King' and 'Xmas Drumhead'; savoy—'Best of All' and 'Ormskirk.'

Red Cabbage is slow to mature; plants from sowings in August are transplanted 6 in. each way in autumn and set out in early spring 18 in. each way. They are ready to cut in late summer.

Cardoon (Cynara cardunculus).—Closely related to the globe artichoke and grown for the blanched hearts. Seed is sown in trenches 18 in. wide and 1 ft. deep; 3 in. of manure is worked into the bottom soil and covered with 3 in. of fine soil. Three or four seeds are dibbled in every 18 in. and covered with a flower pot till visible, and then thinned out, leaving one strong seedling at each station. Protection from sun and late frosts is provided by twigs over the trench, and copious watering is given during the summer. On a fine day in September the plants are blanched by tieing the leaves together and covering with dry hay, 3 in. thick, kept in position by raffia, and earthed up in the same way as celery. Blanching is completed in about a month. Litter over the top protects them from frost.

Carrots.—A light, well-drained soil, enriched with decayed organic matter, is suitable for carrots. No fresh manure should be given, but a light dressing of "National Growmore" fertiliser can be applied prior to sowing. The surface is left rough until sowing time and then broken down to a fine tilth. The first sowing is made in early April in drills ¾ in. deep and 12 in. apart, and a succession is obtained by sowing at intervals of a month until the end of July.

On heavy, unfavourable soils stump-rooted varieties are best grown, long-rooted varieties needing a light soil. Thin out the stump-rooted varieties to 4 in. apart and the longer varieties to 6 in. Thinnings should be removed and the soil pressed firmly back to minimise damage by carrot fly. The early sowings are pulled as required, but the later sowings for winter use should be lifted in October and stored in slightly damp sand in a frost-proof shed, or clamped in the open.

Frames and cloches are sometimes used to obtain early and late carrots. Seed of a quick-growing variety, such as 'Amsterdam Forcing' or 'Early Nantes,' sown in late January under cloches or in frames will provide an early crop; the same varieties sown in frames or cloches in early August will provide young carrots for the autumn. Carrot fly is a bad pest, especially on light soils; the seedlings should be dusted with lindane or dieldrin when 2–4 in. high to prevent the flies from egg laying.

Varieties: globular—'Early Gem'; stump-rooted—'French Short Horn'; intermediate—'Amsterdam Forcing' and 'Early Nantes'; long—'St. Valery' and 'Long Red Surrey.'

Catch Crops.—A term used for quick-growing crops interplanted between rows of other crops. Radishes between rows of broad beans, and lettuce between celery rows provide examples. In this way the best use of a limited amount of land can be made.

Cauliflower.—Broccoli is for all practical purposes a hardy winter cauliflower. Seed is sown ¾ in. deep in a nursery bed from mid-April to mid-May, depending on the variety, and transplanted during June and July on to firm soil, well manured for the previous crop. The plants are set out 2 ft. apart each way; 2 oz. superphosphate and ¾ oz. of sulphate of potash per square yard may be hoed in before transplanting. No nitrogenous manure should be given late in the year.

Varieties: November—'Michaelmas White'; December—'Winter Mammoth'; January—'Snow's Winter White'; February—'Penzance'; March—'Leamington'; April—'St. George'; May—'Late Queen.'

Sprouting broccoli is very hardy, has a more leafy head, and is cultivated in the same way. Purple and green sprouting varieties are grown.

Summer Cauliflowers require a soil which has been limed and manured during the winter; 1–2 oz. per sq. yd. of superphosphate should be given before transplanting. An early sowing in frames

in February or March will provide plants for cropping in June. These should be hardened off and planted in March or April from 18 to 24 in. square, depending on the variety. Seed sown outdoors in April in drills ¾ in. deep will give plants for transplanting in May or June, for cropping from late July onwards. If growth is slow a dressing of 1 oz. per sq. yd. of sulphate of ammonia should be given. Leaves broken over the curds will help to prevent any damage from early frosts.

Varieties: 'Early London' and 'Snowball.'

Celeriac.—A plant allied to celery grown for its edible root, which resembles a turnip but has the flavour of celery; the stems are bitter to the taste and are not eaten. It is used in salads or boiled as other root crops. Seed is sown in gentle heat in March and seedlings pricked out into seed-boxes, 2 in. apart each way. In June, after hardening off, the seedlings are planted out in shallow drills 18 in. apart, leaving 12 in. between each plant in the row. Water freely during the summer and remove side shoots as they appear. Lift the roots in October or November and store in a frost-free shed.

Celery.—Richly prepared ground is required. A trench 15 in. wide and 1 ft. deep is taken out and manure worked into the bottom of the trench. The soil is then returned to within 3 in. of the ground level. Seed should be sown in early March at about 60° Fahrenheit and the seedlings pricked out in deep boxes 3 in. each way and gradually hardened off. Celery seed is very fine, and care should be taken to cover it with only a fine layer of soil; if covered too deeply it may not germinate.

In late May or June set the plants out in staggered double rows 1 ft. apart, with 10 in. between the plants, and water them in. Frequent watering during the summer is required, and a light dressing of nitrate of soda will stimulate them if growth is poor. Before earthing up to blanch the plants, tie the stems loosely below the leaves and remove any suckers. Earthing up begins when the plants are about 15 in. high; the ground should be moist, and the first earthing should only be slight. The second and third earthings, at intervals of about three weeks, should be more generous, but should never reach higher than the base of the leaves, and no earth should fall into the heart. For exhibition purposes brown-paper collars may be tied round the stalks before earthing. The final earthing should cover all the stems right up to the leaves, and the soil should slope away neatly. In winter litter or bracken spread over the plants will help protect them from frost.

Celery fly is a serious pest, and the brown leaf-blisters should be pinched to kill the maggot inside and lindane applied two or three times at fortnightly intervals. Slugs should be discouraged with a good slug killer. Leaf spot, a seed-borne disease, can be prevented by spraying with Bordeaux mixture.

Varieties: white—'Solid White'; pink—'Ideal'; red—'Standard Bearer' self-blanching—'Golden Plume.'

Chervil.—An annual herb sown during March in drills 10 in. apart, and thinned to 6 in. in the rows. Further sowings can be made during the summer. Used in salads and soups.

Chicory.—The young, blanched growths are used in winter salads. Seeds are sown in drills 1 ft. apart in May; the young seedlings are thinned to 8 in. apart and grown on until October or November, when they are lifted and the roots trimmed to 8 or 10 in. long. They are then planted in deep boxes in a moist, sandy soil 5 in. apart each way, leaving 1 in. above the soil surface, and the boxes put in a warm greenhouse or cellar. No light must reach the crowns; one method sometimes used is to cover the crowns with 6 in. of sand. When the blanched growths show through they are about 6 in. high and ready for cutting.

Chives.—These are like small onions, and the leaves are used for flavouring salads and soups. They are easily grown in window boxes and town gardens. Bulbs can be planted in March 6 in. apart and divided when the clusters become too large.

Corn Salad or Lamb's Lettuce.—Occasionally grown for the leaves, which are used in early spring salads. Seed sown from August to October will provide plants for winter and spring use.

Couve Tronchuda.—A large brassica known as "Portugal cabbage," not generally suitable for smaller gardens. Seed is sown in March and the plants set out 2–3 ft. apart each way. The hearts may be cooked in the same way as cabbage.

Cress.—An annual growing rapidly from seed and used as a salad when only the seed leaves have developed. Seed sown as required, in boxes of light, moist soil and covered with brown paper until germination, when it is removed, will provide salad all the year round. The seed is merely pressed into the soil and the boxes kept moist. Cress may even be grown on damp flannel in a window.

Cucumber.—The cucumber of the shops is grown as a specialist crop under glass. Temperatures of 85° Fahrenheit or more may be required, and only occasionally are they grown by the amateur, although cloche and frame culture is now popular.

Ridge cucumbers, which are smaller and prickly outside, may be grown outdoors in summer. Plants from seed sown singly in pots under glass can be planted during late May on ridges of good, well-manured soil or, alternatively, sown on the ridges 1 in. deep at the same date. Water freely during the summer and cut the cucumbers while young to encourage further production.

If cloches are available greenhouse-raised cucumbers can be planted under them, in mid-April. Frame cucumbers are less hardy, but young plants raised under glass can be planted under cloches in early May.

Varieties: ridge—'King of the Ridge' and 'Stockwood Ridge'; frame—'Telegraph' and 'Conqueror.'

Endive.—Used in winter or autumn salads. Seed is sown during April in drills 18 in. apart and the seedlings thinned to 12–15 in. apart. Sowings in June and August will provide a succession. A rich soil and plenty of moisture are the main requirements; before eating blanching is necessary, as the leaves are very bitter. This is achieved by tieing the leaves loosely together and covering the plants with inverted flower pots (with the holes blocked) to exclude the light; frost should be kept out by piling litter over the pots in winter. If cloches are used they can be coated inside with lime-wash to achieve the same effect. Alternatively, plants may be lifted in October and blanched in darkened frames.

Varieties: summer—'Green Curled Paris'; autumn—'Stag's Horn'; winter—'Batavian.'

Fennel.—A perennial culinary herb used in fish sauces and salads. Blanched stems may also be cooked in the same way as celery. Seed is sown in drills 2 ft. apart in rich soil and the seedlings thinned to 18 in.

French Beans.—*See* **Dwarf Beans.**

Garlic.—One or two "cloves" planted in February, 9 in. apart, will provide ample garlic for salads, as only a little is required. After growth is complete in summer the bulbs can be lifted, dried, and stored and some saved for re-planting.

Haricot Beans.—*See* **Dwarf Beans.**

Herbs.—Many herbs are useful in small quantities for flavouring and garnishing, as well as being decorative. If possible, a separate herb garden should be made as a feature in the garden, or they

may be used as edging plants. Perennial herbs, of which borage, caraway, chamomile, chives, fennel, garlic, horseradish, lavender, mint, pennyroyal, marjoram, rosemary, rue, sage, tansy, tarragon, and thymes are the main types grown, should be given a permanent position. Those grown as annuals—anise, basil, coriander, dill, parsley, purslane, and summer savory—can be used as "fill-ins" on the vegetable garden. Brick and cobble paths associate well with herbs, imparting something of the character of the gardens of bygone days, when herb gardens were considered one of the most important features.

Horseradish.—A deep-rooting perennial herb which appreciates a well-manured, moist soil. It is easily propagated from root cuttings and can become a nuisance, as pieces of root left in the soil will make a new plant; care should be taken to lift the complete root when digging it for use. Straight roots planted in spring with the crowns 6 in. below soil level and 1 ft. apart can be lifted for use in autumn; no further treatment is required, apart from keeping weeds in check. Some of the roots should be kept for planting the following spring.

Kale.—Very useful during a cold winter, when other green vegetables are scarce, because of its hardiness. Seed sown in April or May will provide young plants for transplanting 18 in. apart each way in July or early August, on to a site used for peas or early potatoes, in good heart. A catch crop of lettuce can usually be taken from between the rows. The variety 'Hungry Gap' is usually sown in rows 18 in. apart where it is to mature and thinned, leaving 18 in. between the plants. There are many varieties; which types are grown is a matter of personal preference.
Varieties: 'Curled Kale' and 'Hungry Gap.'

Kidney Beans.—*See* **Dwarf Beans.**

Kohl Rabi.—A brassica with a swollen stem base, in flavour and appearance something between a turnip and a cabbage. Seeds sown in April in rows 1 ft. apart are thinned to 1 ft. apart in the rows, and the swollen stem harvested when about the size of a tennis ball. If left to grow it becomes coarse.

Lamb's Lettuce.—*See* **Corn Salad.**

Leeks.—A vegetable which repays planting on a well-manured soil. If they are to follow winter greens, then manure or compost should be dug in after the previous crop is cleared. Leeks may be sown from early March to April in lines 8 in. apart on a prepared seed bed, and the seedlings transplanted as land becomes available during June and July, when about 6 in. high. Thinning in the seed bed should be unnecessary provided the sowing has been correct. The seedlings are set out 9 in. apart in rows 15 in. apart; a hole is made with a dibber, and each seedling dropped in and watered thoroughly. No firming is needed, the watering should tighten the plants sufficiently. Alternatively, drills 4 in. deep and 15 in. apart can be drawn out with a hoe and the plants put in 9 in. apart in the drills.
Regular hoeing is required, and a feed of sulphate of ammonia (1 oz. per gallon of water) can be applied if in poor growth. In September a little earth should be drawn up around the roots, which should, by then, be almost full grown. Leeks are very hardy and can be left in the soil until required for use.
Varieties: 'Lyon' and 'Musselburgh.'

Lettuce.—Two main types are grown: cos lettuce, a summer crop with long, straight leaves that curl inwards naturally or are tied in so that the heart is more or less blanched; and cabbage lettuce, which are broad and spreading, with round cabbage-like hearts, and are grown to supply salad all the year round. Lettuce should be grown on ground manured during autumn or winter, dug and left rough till planting time, when it is broken down and raked to a fine tilth.
Seed, sown in January in frames and cloches, or outdoors in March and at fortnightly intervals thereafter, a little at a time, until September outdoors, or October in frames and cloches will provide lettuce for most of the year. Sow thinly in drills ½ in. deep, in rows 1 ft. apart, and thin out or transplant young seedlings so that they are 9–12 in. apart, depending on the variety. Quick, unchecked growth with adequate moisture is required; a dressing of bonemeal worked into the soil before planting and a light dressing of sulphate of ammonia in water on poor soils will help growth considerably. Aphids may be troublesome, and should be checked by using lindane or malathion.
Varieties: summer—'All the Year Round' and 'Continuity'; early spring—'Arctic King' and 'Cobham Green.'

Maize.—*See* **Sweet Corn.**

Marrows.—Pumpkins, gourds, bush, and trailing marrows all require similar treatment; plenty of sun and water and a rich soil, such as an old hotbed or compost heap, which will provide a porous medium of humus. Seed can be sown singly in pots under glass in March, or outdoors on the site in May. For cloches a bush variety must be used, and greenhouse-raised plants are cloched in mid-April. Plant four or five seeds in groups about 6 in. apart and 1 in. deep and finally thin to two plants 15 in. apart. Protection from late frosts may be necessary. Water copiously and hoe regularly. Cut marrows when about 12 in. long to encourage further fruits. Some can be left until they are full size and cut before the frosts, for storing in a dry, frost-proof place.
Varieties: 'Tender and True' and 'Table Dainty.'

Melons.—Although usually a glasshouse crop, melons can be grown outdoors under cloches and in frames. Seed is sown under glass in April at 60° Fahrenheit, and seedlings can be set out 3 ft. apart in early May. The soil should be manured generously and the seedlings planted on a mound of compost mixed with soil. The plants must be stopped at the fourth or fifth leaf to encourage laterals. Two can be selected to grow on and, when 18 in. long, pinched out to obtain sub-laterals, which will bear the fruit. The female flowers may require pollinating, and on a sunny day a male flower or rabbit's tail can be used to transfer the pollen; as soon as the young fruits swell, remove all but two or three per plant and pinch back the laterals bearing fruit to two leaves from the melon. A feed of dried blood once a week, with plenty of watering (though not saturation!) will help the developing fruits. Light shading may be necessary.
Varieties: 'Dutch Net' and 'Tiger.'

Mint.—Easily grown from suckers in any soil. For winter use a few pieces can be planted in a frame. A number of varieties—'Apple Mint,' 'Peppermint,' and 'Spearmint'—can be grown besides common mint.

Mushrooms.—Growing mushrooms is really a specialist occupation. For the experimental amateur, beds of composted stable-manure are made up in a warm, damp cellar or disused air-raid shelter. Pieces of spawn are inserted when the temperature of the compost has dropped to about 70° Fahrenheit and the whole bed covered with an inch of inert sub-soil. The air temperature should be from 60° to 70° Fahrenheit, and in a few weeks mushrooms may appear. Full instructions will be given with the spawn, but it is advisable to consult a text-book dealing with the culture, as even for professional growers a crop is never certain.

Mustard.—Grown exactly in the same way as cress, but is ready two or three days earlier. If used together, mustard seed should be sown two or three days after cress. Again it is the seed leaves which are eaten.

Onions.—These respond well to good cultivation. The site is dug deeply in winter, manure

incorporated, and left rough until February, when it is broken down to a fine tilth and firmed well. Seed can be sown ¾ in. deep in drills during August and planted in March for exhibition onions, but the usual practice is to sow seed in late February outdoors or under glass in January and transplant during April in rows 12 in. apart with 6 in. between the onions, taking care to keep the bases about ½ in. below the surface. If sown outdoors and thinned the thinnings may be used in salads. Autumn-sown onions are liable to bolt, but less liable to attack by onion fly than spring-sown plants.

Dressings of sulphate of ammonia or nitrate of potash may be given during the growing season, but not later than July. In August the tops are bent over to hasten ripening and the bulbs harvested in a dry spell at the end of the month, first laying them on the ground for a day or two to dry off. They should be stored in a dry, airy place. The chief pest is onion fly, controlled by dusting the seedlings with aldrin at the loop stage. Onion sets are small onions produced the previous summer, stored and replanted in spring to obtain very large bulbs. They are particularly valuable on poor soils.

Varieties: spring sowing—'Bedfordshire Champion,' 'Best of All,' and 'White Silverskin' (pickling); autumn sowing—'Giant Zittau,' 'Sutton's Solidity,' and 'White Lisbon' (salad onions); sets—'Ebenezer' and 'Rynsburger.'

Parsley.—Sow thinly in rows 8 in. apart during March and again in July for a succession of young foliage; thin to 4 in. between plants.

Parsnip.—Grow parsnips on ground manured for a previous crop; if given fresh manure splitting and forked roots occur. Dig the soil deeply, and at sowing time in March, work the soil to a fine tilth. On a soil unsuitable for deep-rooted crops special holes 10–12 in. apart, filled with sifted soil, may be prepared. If this method has to be used four or five seeds are sown per hole; normally drills 15 in. apart and 1 in. deep are made and four or five seeds sown every 9 in. The seedlings are thinned, leaving one at each station. Parsnips should be left in the ground until needed; litter over the rows will ease lifting in frosty weather.

Varieties: 'Evesham' and 'Student.'

Peas.—Dig the ground well in autumn and add a generous amount of manure or compost. Seed sowing begins at the end of February, and can be continued at three-weekly intervals until early July. Under cloches sowings in January and October will lengthen the season. Both early and late sowings should be of a quick-maturing variety. Seed is sown in drills 6–8 in. wide and 3 in. deep, with 2 ft. between drills; the seeds can be scattered thinly in the drill or spaced 3 in. apart in a treble row. Cover with 2 or 3 in. of soil and as soon as the peas are about 2 in. high stake with twigs.

Failures are often due to attacks by birds and field-mice. The former should be discouraged by netting and the latter by trapping. Pea-sticks will be necessary for the taller varieties which should have 3–4 ft. between the rows. With limited space only the dwarf quick-maturing varieties should be used. A summer mulch will keep the soil moist, and picking should be done regularly.

Varieties: 1½–2 ft.—'Kelvedon Wonder,' 'Kelvedon Triumph,' and 'Meteor' (cloches); 2½ ft.—'Onward'; 3½–4 ft.—'Achievement.'

Potatoes.—In general, it is only economic for the amateur to produce an early crop; the main winter supply can be grown if room and labour are available. They should be grown on land well manured the previous season, dressed at planting time with a mixed fertiliser, such as "National Growmore," at a rate of 1½ lb. to a 30-yd. row. The soil should not contain too much lime, as the damage of scab disease is increased.

"Seed" tubers about the size of a large egg are best used, and these can be bought or saved from the previous season's crop. Large potatoes may be cut leaving about three eyes to each part. New stocks should be bought occasionally if the "seed" is home saved to obviate risk of virus. "Seed" should be put in trays during February in a frost-proof shed to sprout, and in early April the "first-earlies" can be planted.

Drills 2 ft. apart and 4–5 in. deep are taken out and the sprouting "seed" planted 12 in. apart in the rows. Maincrop varieties are planted in early May 15 in. apart. The young growths should be protected from frost by earthing up slightly, and a further earthing is done as the potatoes mature. This practice of earthing prevents the tubers near the surface from becoming green when exposed to light, keeps weeds down, and protects the tubers from spores of potato blight, which are washed into the gullies. If growth is poor sulphate of ammonia can be applied at a rate of ½ lb. per 30-yd. row. Early varieties should mature in late July and later varieties in September and October; when the tops (haulm) turn yellow the crop can be lifted, dried for a few hours (too much light will turn them green), and stored in boxes in a frost-proof shed or clamps. No damaged tubers should be stored. Clamps outside can be made by laying straw on a flat site and building the potatoes into a ridge-shaped heap; this is then covered with a thick layer of straw and then by a 6-in. layer of soil, interspersed with straw "chimneys" to aerate the clamp.

SEED POTATOES—Good seed is essential for first-rate crops. Illustration shows (*left*) a well-sprouted tuber, (*centre*) a large well-sprouted tuber suitable for cutting, and (*right*) a poor, badly sprouted tuber.

Potato blight is a common disease, and control by spraying with "Bouisol" before the leaves touch in the rows is effective. Virus diseases, spread by greenfly, are checked by using "seed" from Scotland, where greenfly is less troublesome because of the lower temperatures. Colorado beetle should be watched for, and if found notified to the Ministry of Agriculture.

Varieties: early—'Arran Pilot,' 'Duke of York,' and 'Epicure'; main—'Arran Banner,' 'King Edward,' and 'Majestic.'

Pumpkin.—*See* Melon.

Radish.—Most cultivated ground is suitable for growing radishes; successional sowings at fortnightly intervals from early March until May in drills ½ in. deep should be made. Summer-sown radishes bolt and are hot and tough, but autumn sowings for late salads can be made. As radishes germinate very quickly, they can be sown together with another crop and used quickly, and also enable the rows to be seen and hoed early.

Varieties: 'French Breakfast' and 'Scarlet Globe.'

Rhubarb.—Before planting the ground should be generously manured and deeply dug. Crowns are planted in March, 3–4 ft. apart each way and mulched, but no rhubarb should be pulled until the following year, when a light pull can be taken. Remove any flowering shoots and give a dressing of sulphate of ammonia if growth is weak. Manure well each winter; if early supplies are needed, some of the crowns can be covered with inverted boxes or barrels and a packing of loose straw or bracken. An established, well-cultivated bed will continue almost indefinitely.

Sage.—A hardy shrub for the herb garden easily raised from cuttings. The leaves are harvested and dried in summer.

Salsify (Oyster Plant).—A winter root rather like a parsnip which requires similar growing conditions.

Savoy.—*See* **Cabbage.**

Scorzonera.—A winter root cultivated in the same way as salsify. It has a purplish root instead of the yellow-green one of salsify.

Sea-kale.—A perennial plant native to our sea-shores, which can be either grown from seed sown in March and left for two years to produce forcing crowns or from bought thongs, which are planted during March, 9 in. apart in groups of three, leaving 3 ft. between groups. During summer a manure mulch and nitrogenous fertiliser can be applied. When the tops die down in autumn the crowns are covered with boxes to force and blanch the new growths. Crowns can be covered in succession to keep a supply. Earlier sea-kale can be obtained by lifting crowns in November. These are planted in batches five or six to a pot, watered well, and a second pot, with the hole blocked, placed over them. In a warm green-house or similar position they should develop sufficiently for cutting in about three weeks. Slugs are the chief pest outside, and should be kept in check by a proprietary slug-killer.

Shallots.—A popular crop for the small garden. Shallots are purchased as bulbs, like small onions. A deep, well-manured soil is required, as for onions, and they are planted during February, the bulbs being pressed about half their length into soft soil, 6 in. apart in the rows, leaving 1 ft. between rows. In mid-July the little bunches of bulbs can be lifted. Leave them on the surface to dry for a few days and then store in a dry, frost-proof shed. Some, about the size of a shilling, should be kept for planting the following year.

Spinach.—Sowings from February to May on a well-manured soil will provide a succession during the summer. Sow in drills 1 in. deep and 12 in. apart and thin the young plants to 3 in., and then to 6 in., using the second thinning to eat. A sowing of the prickly variety in August at the same distances will provide a winter crop. When picking gather a few leaves from each plant in the row.

Varieties: 'America' and 'King of Denmark.'

Sprouting Broccoli.—*See* **Cauliflower.**

Sugar Beet.—*See* **Beetroot.**

Swede.—*See* **Turnip.**

Sweet Corn (Maize).—Gardeners should distinguish between the types of maize used for poultry food and those which supply sweet corn for human consumption. It is wise to use cloches for growing sweet corn, as it is only half-hardy and resents transplanting. Seeds sown under cloches in mid-April in two drills 12 in. apart and 1½ in. deep should be placed 1 ft. apart in staggered positions in the rows. More robust varieties may need 15 in. from plant to plant. A soil well manured for the previous crop is best used, and a mulch can be given as soon as the plants are a few inches high. The first cobs should be ready by mid-July, and should be eaten when the cob is milky.

Variety recommended: 'John Innes Hybrid.'

Tarragon.—A herb used for flavouring vinegar. Raised by root division in spring. Cut down and dried for use in winter.

Tomato.—A sunny, sheltered site is required, otherwise ripening outdoors in our climate is uncertain. Sow seeds under glass in late March and harden off the plants in a cold frame or buy plants for setting out in late May or early June. The soil should be thoroughly dug and some artificial manure applied before planting. Allow 18 in. between plants and 2½ ft. between rows, and put in a strong stake with each plant. Keep to a single stem, pinching out side shoots regularly. When four or five trusses are set pinch out the top of the main shoot.

Feed with a liquid manure during summer. Fruit which fails to ripen outdoors can be gathered and stored at about 50° Fahrenheit or the plants laid flat on the ground and covered with cloches, when the tomatoes should ripen. Under cloches plants can be planted out in mid-April instead of late May, gaining six weeks growing time, and the Cloches removed when they become too large.

Potato blight attacks tomatoes, and a spray of "Bouisol" during the first week in August and repeated after fourteen days will control this.

Varieties: 'Market King' and 'Money-maker'; some heavy-cropping sorts have little or no flavour.

Turnips.—Ground manured the previous season should be dug well and dressed with 2 oz. super-phosphate per square yard. An early variety can be sown during April in drills ¾ in. deep and 15 in. apart, followed by successional sowings at three-week intervals as required. The main crop for storage is sown in July and August, and seedlings should be thinned gradually to 10 in. apart. Use when about the size of tennis balls. A sowing can be made in September, left almost unthinned and the tops used as "greens" in spring. In autumn the storage crop is lifted and all undamaged roots put in sand in a shed or clamped. Flea beetle and turnip fly can be checked by D.D.T. at the seedling stage.

Swedes are grown in a similar manner.

Varieties: turnips—'Early Milan' (summer) and 'Green Top Stone' (winter storage); swedes—'Purple Top.'

FERTILISERS AND ORGANIC MANURES.

The elements essential for healthy plant growth may be roughly grouped into classes—first, those required in some quantity, the major elements, nitrogen, potassium, and phosphorus; secondly, calcium, magnesium, and sulphur, which are required in lesser quantities; and thirdly, the trace elements, boron, manganese, iron, zinc, copper, and molybdenum, of which only minute quantities are needed. As well as the elements mentioned, others, such as silicon, aluminium, chlorine, nickel, and sodium, are often found on plant analysis, but the evidence that these are essential is inconclusive, though they may be beneficial to certain crops.

It is important to remember, when adding fertilisers to the soil, that different crops may require relatively more of one element than another, but a balance between all the elements is essential. As an instance, brassicas (the cabbage family) are gross nitrogen feeders, while root crops (*e.g.*, carrots) require far less nitrogen, and an excess may be harmful. A further point to notice is that although an element may be present in the soil the plant may be unable to absorb any because it is being kept in an insoluble state by excess of another element. An instance of this is the frequent yellow and sickly appearance of plants on very chalky soils due to lack of iron, which is present, but locked in an insoluble state by too much calcium.

The elements needed by the plant are in the form of various compounds, such as nitrates and phosphates, and may be applied as artificial fertilisers, which are manufactured, or as humus, which contains most of the foods required and

also provides the essential soil micro-organisms or bacteria, without which the soil would be inert and no plants would grow. Bacteria break down the complicated animal and vegetable matter of which humus is composed to soluble compounds which plants can absorb. Humus can be supplied as farmyard and poultry manure, leaf mould, compost, sewage sludge, spent hops, and from animal by-products like hoof and horn, dried blood, meat and bone meal, and many others.

Nitrogen is mainly concerned with vegetative growth, encouraging leaf and stem formation. It is also contained in chlorophyll, the green colouring matter of the plant, and one of the symptoms of nitrogen starvation is a pale-green colour to the leaf, indicating a lack of chlorophyll. Most of the nitrogen compounds used are soluble, and it is a wise maxim to apply "little and often": if given in large doses much is washed through the soil and wasted.

Nitrogenous fertiliser should not be given to any plant late in the season, as sappy growth, easily damaged by winter cold and frosts, is encouraged. Similarly, at no time should large quantities be given to any plant, as this results in an excess of leafy growth, which is very susceptible to disease and adverse conditions of drought and cold; also plants tend to be later flowering.

Sulphate of ammonia is the most used inorganic nitrogenous fertiliser, and is excellent for spring use on seed beds, lawns, and early crops, and it is contained in most fertiliser mixtures. It makes soils acid in reaction, and if both lime and nitrogen are required, nitro-chalk should be used instead. Other nitrogen fertilisers used are potassium nitrate, which has the advantage of supplying two major elements at once, and is very soluble, and nitrate of soda, often used on beet and mangolds. The latter chemical should not be applied in excess, as too much sodium has a bad effect on soil structure. These inorganic fertilisers are all soluble and quick acting. As a general guide, 1 oz. of the fertiliser to a gallon of water, applied at 1 oz. to a square yard, is a good general summer dressing, given at intervals of two or three weeks. It should always be given after rain or watering, and should be applied to the soil and not to the foliage.

Among organic fertilisers containing a percentage of easily available nitrogen are dried blood, soot, and meat and fish meals. Slower to decompose, and so having a more lasting effect, are shoddy (wool waste) and hoof and horn.

Phosphorus is concerned in the plant with the production of young cells of the root and shoot, and also encourages flower and fruit production and early ripening. Most of the compounds are relatively insoluble (rendering absorption by the plant difficult), and so large amounts can be supplied without deleterious effects, especially on acid soils, where the availability is less than on alkaline soils.

Phosphorus is generally applied to the soil in the form of phosphates, and among these superphosphate of lime is quick acting, and is usually applied at 2–3 oz. per sq. yd. in spring and summer, when the need is greatest. More slow acting is basic slag, a by-product of the steel industry, sold as a fine black powder and containing, besides phosphates, many of the trace elements, as well as a considerable percentage of lime. This is good for application to acid, wet soils, but should not be applied to potatoes owing to the risk of scab disease with the increase in the content of lime. It should not be applied with sulphate of ammonia. Bonemeal is also slow acting and also contains some nitrogen. It is excellent for crops like tomatoes, and is also used extensively for ornamental and pot plants.

Potassium, the third major element, is essential for good flower colour and ripeness in fruits. Dessert apples, potatoes, cereals, and root crops all need potash in some quantity, and if excess nitrogen has been applied a dressing of potash may counterbalance the effect. Sulphate of potash is the main inorganic compound in use. Muriate of potash (potassium chloride), to which some crops are sensitive, is much less used; it should be applied as a winter dressing before the crop is sown to lose the impurities by weathering. Sulphate of potash is purer, and may be applied during the growing season at 1 oz. per sq. yd. on the vegetable plot, and is used in many proprietary fertiliser mixtures.

Wood ash contains variable quantities of potassium, and provided that the ash has not been washed by rain and the potassium leached out, is a useful addition to the soil; bracken, cut during June and July, when large amounts of potassium are present in the foliage, can be composted when green to provide a good supply of the element.

Elements Required in Lesser Quantity.—Calcium, although required in small quantities in the plant, has profound effects on the soil. Its main function in the plant is in the production of the cell walls, but in the soil it helps to bind light soils together and to make the structure of sticky clay soils finer and more workable. Also soils without calcium are acid and tend to lock up some elements in an insoluble form. Addition of calcium changes the acidity, making it slightly alkaline or neutral, and releases the locked elements.

Calcium is applied as some form or derivative of calcium carbonate, commonly known as lime, which can be obtained in various forms. Hydrated or slaked lime (calcium hydroxide) is commonly used on clay soils, and chalk or ground limestone on lighter soils. Calcium is gradually leached from the soil, and it is necessary to replace it, or the soil becomes too acid and many crops will fail to grow. A normal dressing of lime for a vegetable garden is about 4 oz. lime or ½ lb. chalk per square yard every two or three years, and is best applied in autumn as a surface dressing after digging. It should not be applied together with other fertilisers. The amount of lime will depend on the type of soil, but it must be remembered that most vegetables grow best on a slightly acid soil.

Gypsum, or calcium sulphate, is sometimes recommended to supply calcium, but its solubility is negligible, and it is preferable to chalk or limestone only on soils containing salt due to sea flooding. It has been used to help reclaim parts of East Anglia flooded by sea-water during recent years by improving the soil structure. Sulphur, as sulphates, and magnesium, as an impurity in limestone, are usually present in sufficient quantities for the plants' needs.

Trace Elements.—In the case of the trace elements most soils contain enough for the plant, but in certain circumstances deficiencies occur. Iron on very alkaline soils is insoluble and, as it is essential for the production of chlorophyll, deficiency results in the chlorosis of the leaves. It can be rectified by spraying the leaves with "Sequestrene Plus," as can the lack of magnesium and manganese, which may also be deficient on acid soils.

Chlorosis in brassicas and marsh spot of peas are due to magnesium deficiency. Boron deficiency, often occurring on light, calcareous soils, is responsible for brown heart of cauliflower and several other "diseases," mainly affecting the growing point. It can be rectified by applying borax to the soil at about 1 oz. per 15 sq. yd. Zinc and copper deficiencies are unusual in England, but lack of molybdenum has caused whiptail disease of cauliflower. Only minute quantities of the last three are required; more may be poisonous to plants and animals.

Organic Manures.—It should be noted that most of the deficiencies will not concern the amateur, especially if he keeps the ground in good heart with ample organic manure, which contains all the plant foods necessary. Well-rotted farmyard manure from cows and pigs is by far the best organic food, but is scarce now, good farmers returning it to their own land, and generally the material offered is low in nutrients. Poultry manure, which is rich in soluble nitrogen salts, is excellent either applied direct to the soil (not to the growing crop for fear of damage) or composted with straw.

Many substitutes have been devised to use in place of manure, among them sewage sludge, best applied some time before growing the crop, spent hops from breweries, dried seaweed, excellent for potatoes when supplemented by superphosphate, soot, rich in nitrogen, composted town refuse, and the waste organic animal products mentioned earlier. The organic matter in all these materials is essential for maintaining the soil structure and cannot be replaced simply by artificial fertilisers.

Liquid manure, produced by suspending an old sack of animal manure or soot in water for a few days, is useful for the amateur to apply to pot plants and to individual crops like sweet peas, tomatoes, and chrysanthemums. Leaf mould and peat can be used as a mulch and also to supply organic matter to the soil. Sawdust in a well-rotted condition is also useful for inclusion in compost and as a mulch. It is emphasised that it must be well-rotted, and it is advisable to apply a nitrogen fertiliser, such as sulphate of ammonia, at the same time.

Composting of organic refuse from house and garden is much practised by the amateur nowadays.

Compost-making.—The methods developed for making compost heaps are many and various; they depend on three basic principles, good aeration, plenty of moisture, and a nitrogen supply for the decomposition bacteria. A fairly simple method by which much garden and house refuse can be utilised is as follows. An area about 9 ft. by 4 ft. is marked out and all waste vegetable matter—weeds, lawn mowings, cabbage leaves, pea haulm, straw, dead leaves, and hedge clippings —are put in this area and trodden down. Care should be taken not to use diseased material but grass clippings and weeds which have been recently treated with hormone weed-killers may be applied. When the heap is about 9 in. thick it is sprinkled with sulphate of ammonia and superphosphate, at ½ oz. of each per square yard (2 oz. of each for a 9-ft. by 4-ft. plot) and any wood ash available, and then sprinkled with 4 gallons of water and covered with an inch of soil. This process is repeated with 9-in. layers of rubbish until the heap is about 4 ft. high, when it is better to begin a second heap. A sprinkling of ground lime may be given as each layer is added, but should not be applied until after watering to avoid reaction with the sulphate of ammonia.

The completed heap should be watered occasionally, and after about a month or six weeks, if time permits, it can be turned completely over, watered again, and re-covered with soil. The heap may then be left until rotted, and the compost can be dug in as required; any unrotted material can be used as a basis for a new heap. The time taken for rotting will vary with the time of year and material used, but generally a compost heap made during the summer should be available for autumn use, and one made during the autumn ready for spring use.

There are a number of compounds on the market, known as compost makers, which are said to accelerate the decomposition, but in general a heap made in the way described is eminently satisfactory, and although requiring a certain amount of labour, is the least expensive way of obtaining humus for the garden. This latter point is extremely important nowadays with the scarcity of animal manure and the high costs of both inorganic and organic fertilisers. Prices are, of course, not static, but comparatively the organic manures, such as dried blood, hoof and horn, and guano, are more expensive than the inorganic salts, but these lack humus, which is an essential of a well-cultivated soil.

General Fertiliser.—Many firms supply compound fertilisers containing given amounts of the main nutrients needed, in either liquid or powder form, and some are made up with quantities of nitrogen, potassium, and phosphorus suitable for specific crops like roses, tomatoes, and chrysanthemums. A general fertiliser which can be made up by the amateur is as follows:

7 parts by weight superphosphate.
5 parts by weight sulphate of ammonia.
2 parts by weight sulphate of potash.

All the ingredients are easily obtained from local sundriesmen, and a mixture of this sort will supply a good general feed.

Green Manuring.—Another method of enriching the soil with organic matter is green manuring, which has been practised for some time by farmers and can no doubt be adapted to the gardener's purpose. Green manuring consists of planting a fast-growing catch-crop and ploughing the mature crop back into the soil. Legumes are especially good for this, as certain bacteria in their roots can "fix" the nitrogen in the air. Field peas, sown at 4 oz. per sq. yd. and Italian rye grass at 2 oz. per sq. yd. are commonly used, and clover and annual lupins are also suitable.

If sown after an early crop on land needing organic matter the green manure may be dug in during late summer. Alternatively, if the land is not being cropped at all during the year two green-manure crops may be grown; an early sowing of field peas in April may be dug in during July, and a further sowing of field peas or Italian rye grass sown immediately after may be dug in following the first few frosts.

New chemicals often appear on the market at exorbitant prices and with fantastic claims as to their value as "soil conditioners" and the like. Contrary to this generalisation, in recent years a chemical known as "Gibberellin" has been used to increase the growth of certain plants. It is now available to the amateur, but should be used with care and mainly in a spirit of experimentation, as no conclusive proof of its efficacy has yet been put forward.

GARDEN PESTS.

Every garden abounds in insects and other small creatures, but comparatively few species are pests which feed on plants. The great majority are quite harmless, while many are positively beneficial and help to keep the number of pests under control by catching and eating them. Every good gardener should make it his business to be able to differentiate between friend and foe. This is not always easy, but the speed of a creature's movements may often provide a clue. Fast-running, active creatures, such as the black ground-beetle or the centipede, are usually beneficial, while the slow-moving and sluggish ones, *e.g.*, wireworms, aphids and caterpillars, are usually pests. This is by no means an infallible rule, but it is handy to remember when in doubt.

The good gardener should also get to know the pests which are most prevalent in his district and which can be expected to crop up year after year. The first principle of good control measures is to act while an infestation is still in its early stages and before a great deal of damage is done. When one knows what to expect, steps can be taken to prevent an attack or to stop it developing to serious proportions.

Also, from the experience of past years one can often forecast whether a pest is likely to become numerous enough to make chemical treatment worthwhile. Remember, insecticides can become an expensive item, and there is little point in using them if the damage is negligible. In these circumstances insecticides may eventually increase the numbers of pests, since the treatment will also have killed off many of their natural enemies which had hitherto kept the pests under adequate control. In addition, good cultivation and general garden hygiene helps to reduce the numbers of pests.

The common pests of garden plants can be roughly divided into four main groups.

I. Root Pests.—These destroy the feeding mechanism of plants or tunnel into fleshy tap roots, tubers, and bulbs. Attacked plants make poor growth, and may eventually wilt and die.

Some insects are general root-feeders. These include (*a*) **Swift Moth Caterpillars**, soft, white caterpillars with reddish-brown heads; (*b*) **Chafer Grubs**, large, C-shaped, whitish grubs with chestnut-brown heads; (*c*) **Wireworms**, long, cylindrical, yellowish-brown grubs with a hard shiny skin; and (*d*) **Leatherjackets**, greyish-black grubs with a wrinkled, leathery skin. These are particularly prevalent in recently cultivated grassland or in gardens surrounded by fields, and will attack the roots of a wide range of plants. Chafer grubs, however, are particularly fond of the roots of shrubs, and wireworms will often tunnel in potato tubers and other fleshy roots, whereas leatherjackets prefer the roots of grasses, and may cause browning on large patches of lawn.

Badly infested ground should be dressed with aldrin or lindane dust when cultivating, working the dust into the top 4 in. of soil. Where this is not possible, *i.e.*, on lawns or around established shrubs, the liquid form of the insecticide should be watered into the soil.

Cutworms are stout, fleshy caterpillars, varying in colour from greyish-brown to dingy green. They feed on roots during the day, but at night come to the surface and feed at the base of the stems of plants, causing them suddenly to collapse and wither. Brassicas and lettuce are commonly damaged in this way. Infested ground should be dusted with aldrin or D.D.T.

Millepedes are hard-skinned, cylindrical creatures, brown or black, with numerous short, hair-like legs. They are slow-moving and curl up when disturbed. They should not be confused with the active, long-legged centipedes, which are beneficial. Millepedes commonly extend the damage made by other pests, such as slugs and wireworms. They also bore into the sown seeds of peas and beans. During the day they hide in dark, damp places, such as long vegetation or under stones and pieces of wood. Such hiding-places should be removed or dusted with lindane or aldrin. Drills for pea and bean seed should also be dusted before covering.

Weevil Grubs, small, curved, white grubs, may infest the roots of pot plants and plants in rockeries. Such plants should be removed, the roots cleaned, and replanted in soil which has been dressed or mixed with aldrin dust. Where it is not practicable to remove the plants they should be watered copiously with a liquid form of these insecticides and soil dressed properly at the earliest opportunity.

Slugs need no description. They vary greatly in colour. The most destructive are the underground keeled slugs, small, grey-black in colour, which tunnel in roots, tubers, and bulbs. There are also several foliage-feeding species which rasp holes in the top parts of plants. Slugs like wet conditions, and much can be done to control them by ensuring that the soil is well-drained and that long, tangled vegetation is removed.

Poison baits can be bought or made by mixing 1 oz. metaldehyde with 3 lb. bran (or bonemeal for keeled slugs). The bait is sprinkled over the infested ground or distributed in small heaps and protected from the rain. There is also available on the market a metaldehyde spray for dealing with the foliage-feeding types.

Cabbage Root Fly attacks brassicas and wallflowers. The small white maggot eats away the side roots and tunnels in the main root, causing the plant to wilt and collapse. The roots of young seedlings should be dipped in aldrin or dieldrin before planting out. Alternatively, the plants can be given a drench of aldrin or dieldrin within four days of planting out. The maggots also tunnel in radishes and turnips, and this can be avoided by dusting the seed drills with aldrin.

Carrot Fly.—The maggot of this fly tunnels in carrots and parsnips. Where the pest is serious it is best to delay sowing until the end of May. If possible, seeds should be sown in exposed, windy places, which are avoided by the egg-laying flies. Seedlings should be dusted or sprayed with lindane or dieldrin when 2–4 in. high, particularly in late May or early August, the peak periods for egg-laying.

Onion Fly maggots tunnel into the bulbs of onions, leeks, and shallots, causing the foliage to collapse. Dig out attacked plants carefully, ensuring that parts of them are not left in the soil, and burn them. To prevent attacks dust around the seedlings with lindane or aldrin when they are at the "loop" stage, *i.e.*, about 1 in. high, and again ten days later.

Narcissus Bulb Flies are serious pests of narcissi and also snowdrops and other bulbous plants. The maggots burrow in the centre of the bulbs, causing them to rot. All soft bulbs should be burned and the remainder immersed for three hours in a solution of lindane containing a wetter. To prevent future attacks immerse the bulbs in aldrin for fifteen minutes before planting out. Alternatively, dust around the necks of growing bulbs with lindane at fortnightly intervals from the end of April until the end of June.

Insects which feed above ground include:

II. Sucking Pests pierce the tissues of plants with needle-like mouth parts and suck the sap. This devitalises the plant, checks growth, and causes wilting. Some species cause distortion of leaves and young shoots, and aphids, suckers, scale insects, and mealy bugs excrete a sugary fluid which disfigures the foliage, attracts ants, and allows the growth of sooty moulds.

Aphids, *i.e.*, blackfly, greenfly, etc., are serious pests which attack almost all plants and multiply rapidly in warm weather. They feed on the shoots and undersides of the leaves, and many species are responsible for the transmission of virus diseases. Infestations should be treated as early as possible. Malathion, lindane, D.D.T. emulsion, and nicotine are all good sprays to use, and should be applied to the undersides of the leaves. With the advent of these sprays the control of aphids on roses and broad beans, for example, is no longer a serious problem.

Tree fruits should be sprayed when the buds are bursting and again when the flower buds are still green. Currants should be treated at the "grape" stage, but lindane should not be used on this fruit. Tar oil, applied to deciduous woody plants while they are completely dormant, will kill the overwintering stages of these and many other pests. It does not, however, give a good winter control for **Woolly Aphid** on apples. This pest is best controlled by spraying at the pink-bud stage with B.H.C. with a succinate spreader added. Small colonies on the bark can be eradicated by painting with 10% tar oil.

Some aphids feed underground on roots, particularly of lettuces, currants, and cacti. Where practicable, infested plants should be lifted and the roots cleaned and sprayed before replanting in clean soil. Otherwise water them copiously with malathion or lindane.

Scale Insects are often found in greenhouses, but also occur out-of-doors on trees and shrubs. Flat or dome-shaped, these creatures spend most of their lives immobile, and they do not at all resemble insects, or even appear to be alive. Again tar oil is useful for killing the overwintering stages on deciduous woody shrubs which are dormant. Plants which are in leaf should be sprayed with malathion or nicotine/white oil emulsion two or three times at fortnightly intervals. These substances are more effective if as much as possible of the scale is first removed by means of a sponge, brush, or scraper with water in which soft soap has been dissolved. **Mealy Bugs** are common pests of greenhouse plants, and should be given the same treatment as scale insects.

Capsid Bugs are very active insects which cause considerable damage to fruit trees and bushes and also to various ornamental plants, principally

chrysanthemums and dahlias. They feed on the young leaves, causing distortion and raggedness, and on the buds, which later produce misshapen blooms. These insects, green or reddish in colour, can be controlled by spraying with lindane or D.D.T. when the flower buds are still green (tree fruit) or with D.D.T. at the "grape" stage (currants). Herbaceous plants should be sprayed two or three times at three-weekly intervals, starting when the plants are young and before the damage is seen. The ground under the plants should also be sprayed to kill those insects which fall off during treatment.

Leafhoppers are small, yellowish-green insects like aphids but much more active. They feed on the undersides of the leaves of a variety of plants, causing them to become speckled with yellow. Roses are commonly attacked. The treatment given to capsids on herbaceous plants will control these also, the sprays being directed to the undersides of the leaves.

Whiteflies are serious pests in greenhouses, and also occur out-of-doors on rhododendrons and other evergreen shrubs. The adults are like miniature moths with white wings, and the young are small, scale-like creatures, generally greenish in colour, which feed without movement on the undersides of the leaves. To control this pest D.D.T., lindane, or malathion should be used as a spray or smoke, two to three applications being given at fortnightly intervals.

Red Spider Mites are extremely small creatures, red or greenish in colour and just visible with the naked eye. They feed on the undersides of the leaves of many greenhouse and outdoor plants, including fruit, causing the leaves to turn sickly yellow. Control is difficult, the most effective materials being malathion, derris, summer ovicides, or azobenzene smoke. The directions on the labels of these products should be followed carefully.

III. Biting Insects have chewing and biting mouth parts which are used to cut away pieces of plants.

Caterpillars (the young stages of moths and butterflies) are the best-known pests in this group. They vary in size and colour according to the species, and most plants are liable to be attacked. These should be sprayed or dusted with D.D.T. or derris as soon as damage is seen. On fruit trees D.D.T. should be used when the fruit buds are still green, and again at the pink-bud stage if the infestation is serious.

The **Codling Caterpillar**, which tunnels in apples, is controlled by spraying with D.D.T. at the end of June and again three weeks later. Since this latter treatment tends to encourage red spider mites, it is advisable to add to the D.D.T. one of the materials recommended for these pests.

Sawfly Caterpillars are very similar to those above, and commonly attack gooseberry and rose foliage. They can be controlled by spraying with D.D.T., derris, or lindane. Attacks by the **Apple Sawfly**, which burrows in young apples and forms ribbon-like scars on the skin, can be prevented by spraying with lindane seven days after 80% of the blossom has fallen.

Beetles and Weevils which feed on foliage are usually best controlled by spraying or dusting with D.D.T. To kill the tiny **Flea-beetles** which eat small holes in the seedlings of brassicas and turnips, treat the plants at fourteen-day intervals until they reach the "rough-leaf" stage.

The golden-brown **Raspberry Beetle**, which feeds on the flowers and whose grub tunnels in the fruit, is eradicated by D.D.T. or derris applied ten days after full bloom and again ten days later. For other common pests in this group, *e.g.*, **Vine Weevil, Clay-coloured Weevil, Pea and Bean Weevil**, etc., apply the D.D.T. as soon as the damage is first seen.

Earwigs feed at night on the foliage and flower petals of many plants. They hide by day inside flowers, in the folds of leaves, and in nooks and crannies on the ground, under flat stones, etc. These pests are killed by D.D.T., applied to the plants (but not to open flowers) and to their hiding-places.

Leaf Miners are very small grubs which tunnel between the upper and lower surfaces of leaves, forming pale blisters, as on lilac, holly, celery, etc., or long, twisting galleries, as on chrysanthemum, pea, and tomato. In small infestations the affected leaves should be picked off and burned. Otherwise spray with lindane as soon as the damage starts, giving three applications at fourteen-day intervals.

IV. Eelworms are microscopic pests which are invisible to the naked eye. They are able to live for very long periods without food and are extremely difficult to eradicate. The most common species are:

Stem and Bulb Eelworm, which infests narcissus, phlox, strawberry, hyacinth, onion, and other plants. Infested plants show distorted foliage and dwarfing and gradually deteriorate. They can only be sterilised by immersion in hot water kept at well-defined temperatures for one to three hours, but expert diagnosis and advice should be obtained before this or any other control is attempted. Infested ground must be kept clear of any host plants for at least three years to starve out the eelworms.

Chrysanthemum Eelworm causes the formation of yellowish blotches between the veins of chrysanthemum leaves, which later turn black and drop off. In severe infestations the blooms are undersized and malformed. Expert advice should be obtained before control measures are attempted.

Potato Root Eelworm is a serious and widespread pest of potatoes, causing the plants to become stunted and sickly, giving very poor yields. The pest can only be kept in check by crop rotation, potatoes being grown on the same ground only once in four years. This is difficult in small gardens, and where land becomes heavily infested the only remedy is to rest it from potatoes for at least five years.

The Purchase and Use of Insecticides.—To ensure that an insecticide will do what the maker claims, it is advisable only to buy brands which have been tested and approved by the Ministry of Agriculture. This can be ascertained by the presence of an Approval Mark (**T30**) on the label. Read the directions and follow them carefully. Over-strength insecticides can cause damage to plants, and certain plants (usually listed) can be injured by some insecticides at any concentration, *e.g.*, cucumbers, marrows, etc., by D.D.T. and lindane. Never apply insecticides to flowers in full bloom, otherwise many valuable pollinating insects will be killed.

DISEASES OF PLANTS.

Plant diseases are important because they can cause great loss not only in growing crops but also in the produce after it has been harvested and stored. The skill in growing crops is wasted if they are destroyed by disease, and many people know the wastage of potatoes through blight disease in winter stores and rotting of onions when they decay through neck rot disease. For these reasons the keen gardener must take notice of

diseases and use the knowledge available to him in checking them wherever possible.

The most important point to remember about plant diseases is to recognise the first signs so that the remedy can be applied at once. In greenhouses this is of great importance because the atmosphere is warm and moist, and in such conditions diseases flourish. It must also be remembered that the same crop is often grown in the same soil in a greenhouse so that we get a build-up of disease, and this causes the well-known "soil sickness." This means that new soil must be brought in or the old soil enriched and also sterilised by steam or by chemicals. Even frames and propagating pits require periodic cleaning up by a disinfection treatment.

Unlike insect pests, the actual cause of a plant disease cannot be seen with the naked eye, and microscopic examination is required for its detection. The scientists who study diseases are called plant pathologists, and these are stationed

THE APPROVAL MARK—An officially approved crop-protection product shows on its label this design.

at universities and other institutes throughout the country, where they carry out research on various plant troubles and advise on suitable remedies for checking them. It is obviously necessary to understand the exact cause of a disease and how that cause operates before a means of checking the trouble can be devised. The advice can then be passed on to growers, farmers, and the gardening public.

The presence of disease in most cases can only be detected by the symptoms shown by the affected plant, which is called the "host" plant. The actual cause must then be determined by careful examination in the laboratory, which is done by the pathologist.

Plant diseases in general are divided into three classes as follows: 1. Fungus and Bacterial. 2. Virus. 3. Functional Disorders.

1. Fungus and Bacterial Diseases.—The first kind called fungus diseases are caused by the attack of fungus parasites; examples being the well-known club root of cabbages, potato scab, apple scab, and plum brown rot. These parasitic fungi are microscopic and composed of fine threads, but they attack plants and penetrate them either through wounds (insect bites, hail damage, pruning cuts) or directly through the surface cells (epidermis). The threads grow into the plant, killing the cells and absorbing their contents. There is usually some discoloration or even decay of the tissues around the point of infection, but it is possible for the plant to show distress in one part although the parasite is at work some distance away. Examples are silver leaf in plums and the honey fungus, which kills trees by attacking the roots.

The fungus spreads by means of spores which are equivalent to seeds in flowering plants but which are microscopic in size. These spores are produced on the surface of the plant in enormous numbers and are blown (wind), splashed (rain), or carried (insects, etc.) in all directions to alight on other healthy plants, where they germinate and spread the disease. This occurs in the growing season, but when winter approaches, the parasite forms tough, resting bodies of one kind or another, and these are resistant to extreme cold.

They overwinter in the soil or in the surface of tree bark, etc., so that in the following spring they can germinate and cause disease again. So we get the reappearance of such troubles as damping off in seedlings, scab in apples, brown rot in apples and plums, foot rot in peas, wart disease in potatoes, mildews on all kinds of plants, and so on. This question of soil contamination by overwintering spores is one of the most serious in the fight against plant disease.

The signs of fungus and bacterial diseases are varied, and may show as yellowing, silvering, brown spotting, or blackening of leaves (potato blight, rose black spot, celery leaf spot, antirrhinum rust), as stunting (cabbage wire stem), as pustules and cankers in stems (coral spot, apple canker), as gumming or dieback in branches (rose canker, plum dieback), as galls, warts, witches brooms, or other malformation (club root in cabbages, crown gall, leafy gall, peach leaf curl), as dry or soft rots of fruits, tubers, vegetable bulbs, and corms (gladiolus dry rot, potato dry rot, iris rhizome rot, celery heart rot), and many other abnormal conditions. Sometimes only a part of the plant is affected and can be removed, *e.g.*, branches showing attack by coral spot or one of the large bracket fungi seen on trees, these having gained entrance through a wound.

2. Virus Diseases.—This class of disease is becoming increasingly important as more is discovered about them, although research on them is a comparatively recent development. A virus disease is caused by infection with a virus, and the exact nature of this is not yet clearly understood, but it is so small that it cannot be seen with ordinary microscopes. Its detection is therefore not easy, but when the sap of a virus-diseased plant is injected into a healthy one it causes the disease.

In nature this spread is brought about by biting and sucking insects, which are referred to as **Vectors.** They transmit the virus by feeding on infected plants and then travelling to healthy ones, on which they feed and so spread the disease. Most viruses are transmitted by aphids (greenflies).

In the garden and nursery they can be carried from plant to plant by pruning knives or by the fingers in the process of trimming plants such as tomatoes, melons, and cucumbers or by the use of the knife in taking cuttings. In general, the virus does not kill a plant quickly but tends to cripple it and cause a slow deterioration. Infected plants cannot recover but remain, sometimes for years, as sources of infection on which insects feed and carry on the disease. So viruses may increase in lily stocks, strawberry beds, and raspberry plantations unless virus-infected plants are removed and aphids strictly suppressed.

The signs of virus disease are of different kinds, but the commonest are those of the type called mosaic, in which the leaves show a mottling with light-green or yellow patches scattered in irregular fashion on the darker green of the leaf. There may be also some reduction in the leaf blades. These symptoms can be seen in the mosaic of cucumber, vegetable marrow, lettuce, cabbage, turnip, tomato, delphinium, primula, dahlia, apple, raspberry, and many other common plants. In some, such as lilies, daffodils, and onions, the mosaic is more in the form of stripes down the leaf blades.

Another virus symptom is flower "breaking," where the normal colour of the petals is broken by streaks and spots of white, and this can be seen in tulip, wallflower, pansy, stocks, or carnations affected by the mosaic virus. Other viruses cause bronzing of the top leaves (as in tomato spotted wilt) or small light-coloured rings arranged in concentric circles (as in dahlia ring spot) or even reduction of leaves until they are tendril like (as in tomato fern leaf). Sometimes there is malformation or even proliferation, producing innumerable stunted shoots, as in blackberry dwarf disease.

The important point to note about these virus diseases is that every part of the plant is quickly

infected, so that the sap is infectious to other plants of the same kind. The virus is present in all parts, and for this reason it is useless to propagate from a virus-infected plant. This means that all the scales and offsets from bulbs such as lilies and tulips, all the tubers from potatoes, and all cuttings from herbaceous plants which are taken from a virus-infected plant are useless, because they will carry the virus. They should be destroyed, and the only exception is where the plant is greatly valued, in which case seed can be taken from it before it is destroyed. In general, viruses do not travel in the seed, and only in one or two cases is seed infected, and this only in negligible quantity.

3. Functional Disorders.—This third class of disease is often called non-parasitic, because unlike the previous two kinds there is no parasite involved, and these troubles are therefore not infectious. They are due to faulty cultivation or unsuitable environment, in which soil conditions or climate affect the plants adversely. In this group we include cases of unsatisfactory growth due to waterlogging, drought, frost, high temperature, damage by fumes or atmospheric pollution, or even excess lime.

Perhaps the most important kinds of trouble in this class are the so called **Deficiency Diseases**, where the plants suffer from shortage of some important food. This may be one of the common food substances, such as nitrogen, potash, or phosphate, and details will be found under the section on manures and fertilisers (**T25**).

CONTROL OF DISEASES.

1. Garden Hygiene.—The control of plant diseases can be dealt with only briefly, but to begin with we must emphasise the value of good cultivation as an insurance against losses from disease. Robust plants are better able to stand up to disease than sickly ones, and everything in the way of proper drainage, soil aeration, proper spacing, sensible feeding, and so on, will help to keep the plants vigorous, and this is the first line of defence against diseases. Garden hygiene is important, weeds need to be kept down, wounds in trees and shrubs covered with a good paint against infection, new stocks examined carefully, seed bought only from reliable sources, diseased plants burnt, and dead material regularly removed from plants, especially in greenhouses.

2. Soil Sterilisation.—There are other precautions, among which the sterilisation of the soil in greenhouses by means of steam or chemicals is of some importance. Outdoors this is not possible, but rotation of crops is a most useful system in helping to avoid disease. Disinfection of frames, propagating pits, and seed boxes by formalin or cresylic acid are other useful measures.

All these operations aim at destroying the resting spores of fungus parasites responsible for such diseases as tomato leaf mould, gladiolus dry rot, damping off in seedlings, root rots, and downy mildews of many kinds in young plants such as stocks, cheiranthus, cineraria, tomato, aster, and calceolaria when grown in boxes or pots.

3. Disease Resistant Plants.—The use of disease-resistant varieties of plants is very desirable, but there are not many kinds available, and often the resistant kind does not possess flowers or fruit of such fine quality or flavour as the more susceptible kind. The outstanding success of this kind is that of potatoes immune to the dreaded wart disease, and these can be grown safely in the most heavily infected land. There are antirrhinums resistant to rust disease, and there is resistance in some degree in the case of delphinium mildew, potato blight, tomato leaf mould, and some others. Research goes on to discover still more, because any such plants are always worth a trial.

4. Treatment of Seeds and Bulbs.—For seed-borne diseases seed treatments may be done with an organo-mercurial seed dressing, or even by immersion of the infected seed in warm water.

In some diseases, for example, tulip fire, we can protect the bulbs from the danger of infected soil by raking in a powder such as "Botrolex" when planting the bulbs, and a similar treatment is done with calomel dust against club root in beds intended for sowing brassica seeds.

5. Fungicides.—Even after all this, a disease may still appear in the crop, and more direct action must be taken. It is then necessary to protect the plants by means of a **Fungicide**. This is a chemical which is poisonous to fungus parasites but which will not harm the crop plant (host). Fungicides are used as wet sprays or in powder form as dusts, and they are sprayed or dusted all over the plants to protect them from infection by diseases.

The object of the treatment is to cover the plants with a film of the fungicide so as to protect the still healthy ones. To help the spray fluid to spread over and adhere to the foliage another substance, called a wetter, spreader, or sticker, is added to the spray, but sometimes this is already included by the manufacturer.

5. (*a*) Sprays.—Sprays are applied by means of machines called sprayers which vary from small, hand-syringe types giving a continuous jet of spray to those pumped up to a pressure and carried on the back (knapsack machines), and so on to the large machines driven by a petrol engine, which deliver the spray at a high pressure. It is necessary to have a suitable nozzle giving a fine mist-like cone of spray which settles on the foliage and is not wasted.

5. (*b*) Dusts.—Dusts are similar chemicals produced in such finely divided form that the powder can be blown over and on the foliage almost like a fog. This is best done after a shower of rain or after a heavy dew. The machines used are far more varied in design than spraying machines. There are small hand dusters worked either like a small pump or like a bellows, of which the "Acme" is a good example, and there are those which are carried on the back and worked as a double-bellows action or on the front of the body with a rotary-fan action. It is important in gardens to clean and dry the machines after use, and small sprayers may be best put upside down to drain for a time after use.

The substances used as sprays and dusts against plant diseases for many years have been copper and sulphur and their compounds. Perhaps the best known copper-containing spray is "Bordeaux Mixture," which is still a good spray, but which has been largely replaced by colloidal copper available under trade names such as "Bouisol" for such diseases as tomato blight, etc. Sulphur is used extensively as lime-sulphur against apple scab and as colloidal sulphur against the powdery mildew diseases. As dusts, copper is mixed with lime to give copper–lime dust and sulphur is used alone either as flowers of sulphur or green sulphur.

5. (*c*) The Newer Fungicides.—In recent years much research has been carried out in tests to see whether other chemicals have value as fungicides, and the search has been in the field of organic chemistry and among all kinds of these chemicals. Tests of this kind take a long time, but a few substances have already been picked out as showing great promise, and we can mention "Captan," which is so good against apple and pear scab, "Zineb" aginst tomato leaf mould, onion mildew, and tulip fire, "Karathane" against any of the powdery mildews, such as american gooseberry mildew, strawberry mildew, vine and peach mildews, as well as the same diseases on ornamental roses, delphiniums, michaelmas daisies, and the like.

6. Control of Viruses.—The control of virus diseases is very different, because in this case the only spray treatments likely to be of use are those designed to keep down insects. The other necessary control measure is to remove and destroy the virus-infected plants, which are a danger as sources of infection.

This is best done when the plants are young, so that any young marrows, cucumbers, dahlias, delphiniums, sweet peas, lupins, lilies, etc., which show virus symptoms as commonly revealed in leaf mottling and poor growth should be removed as soon as detected. Propagation should be done carefully, so that young stock is not propagated from stocks of strawberries, raspberries, and all kinds of herbaceous perennials which show signs of virus infection. Even the knife used for taking cuttings should be wiped occasionally on a rag dipped in a good disinfectant.

7. Prevention of Functional Disorders.—In the case of Functional Disorders (non-parasitic diseases) it is not always easy to advise remedies. Where the soil conditions are faulty attention can be directed to improving drainage if necessary or counteracting dryness by digging in humus, irrigating, and general mulching. Dryness at the roots of tomatoes causes loss of fruit, and so does extreme dryness in the air of the greenhouse, but these should be adjusted fairly easily.

Hail damage can spoil many crops, but robust foliage may help a little to lessen the damage. Late frost damage to fruit in some areas can be lessened by various methods of cultivation and planting. The effects of drought can be aggravated by shortage of certain foods, especially potash, so that even here some attempt can be made to avoid loss. Excess liming may cause food shortages by causing the appearance, in the leaves, of a yellowish or even whitish colour, which is known as lime-induced chlorosis. The real reason may be lack of iron or manganese due to the excess lime in the soil, but recently very good results at counteracting this condition have been obtained by using the substance known as "Sequestrene Plus."

Another method of treating these food shortages is to spray the young foliage in early summer with the required element in a very weak solution. They can even be included in sprays used for keeping down diseases or pests. It must not be forgotten that even the ordinary foods, such as nitrogen, potash, and phosphate, may sometimes be in short supply, and the effect can be seen by the trained plant pathologist. In these cases the effect may not always show clearly in the growing crop, but may appear long afterwards in the stored fruits and vegetables, which as a result deteriorate and break down long before they are required for use.

The present-day methods of cultivating large numbers of the same plant in one spot tend to increase the risk of large-scale disease attacks. Modern plants may be highly bred and selected for great purity of strain. Indeed, they have often been chosen for fine quality and flavour, with little regard to their ability to resist disease, so that the gardener must always be ready to give them the protection they may need.

USES OF MODERN WEED-KILLERS.

The control of weeds by chemical means is one of the greatest advances of recent years, mainly resulting from a chance discovery made during the War. Occasionally, troubles have arisen in not following makers' instructions. Sometimes the damage has been most unfortunate, as the majority of herbicides are toxic, in varying degrees, to a wide range of plant life. In the main, controls are determined by circumstance, as typified in the following cases:

Open Ground.—On ground free of crops all plant life can normally be killed by watering the herbage with sodium chlorate at 1 lb. to a gallon of water. In some cases repetition may be necessary. In using this method it should be remembered that treated ground will remain toxic to plant life for a period of up to six months; where doubt exists about the presence of sodium chlorate still in the ground, then it is advisable to wait for the appearance of annual weeds. Further to this, the chlorate is liable to seep through the soil and affect plants for some distance away. It should always be handled with care and stored in closed metal containers. Clothes which have been saturated in the solution and then dried are highly inflammable.

At one time arsenical weed-killers—which are very poisonous to humans—were widely used, but they have now been superseded to a large extent. If a considerable area of open ground is to be treated and the foliage is dry a fair control can

A B

COUCH GRASS (A)—A shallow-rooting weed, nowadays easily eradicated by chemical means (see **T33**). HORSETAIL (B)—Usually a persistent weed of low-fertility soils. Botanically it is a poor, but interesting survivor of a large race of prehistoric plants. Details of its control will be found on **T34**.

be established sometimes with a ooded flame gun, but it is seldom possible to kil the roots of many weeds.

Cultivated Ground.—Where grasses of all sorts, including couch grass and annual grass, are growing on cultivated ground around woody or perennial crops a control may be established by watering with "Dalapon." This is a new herbicide of American origin and is of great interest, but full details about its use should be obtained from the manufacturers before making an application.

If annual plants like groundsel and chickweed are found under similar conditions the plants may be eliminated with "Herbon." Here again, it is important to have full information about the preparation and to apply with care.

Garden Paths.—On any surfaced path or drive a first-rate control of weeds can be maintained by watering with a residual herbicide such as "Weedex." As this preparation is virtually insoluble in water, it does not seep through the soil as sodium chlorate would, and therefore it can be used near garden crops and grass edgings. Further to this, it is not easily washed from the soil and remains active near the surface for up to twelve months. Notwithstanding, the herbicide should not be used carelessly.

A dilute solution of sodium chlorate with 4–6 oz. to a gallon of water may be applied, but it is liable to affect garden plants near by, and for this reason application should be confined to the centre of the path, thereby leaving room for the chlorate to seep through the soil.

Lawns.—The majority of weeds in turf can be easily eradicated with formulations of 2,4-D such as "Dicotox" or "Verdone." In particular, daisies, plantains, dandelions, and all broad-leaved plants are susceptible, although it may be necessary to repeat the dose after ten days. The best time to do the work is on a warm, fine day in the spring when the plants are growing actively and there is the prospect of fine weather to follow for twenty-four hours. The action of the herbicides is rapid, and grass may be cut after a couple of days, composting with mowings in the normal way. It appears that the hormones are not injurious to bacterial life in the soil and in a few weeks break down into harmless substances.

Where bulbs are naturalised in grass, steps to control weeds should not be taken until the foliage of the bulbs has died down and the bulbs are dormant. Thus, as a general rule, control measures are best applied throughout July.

To deal with weeds in turf where there arises the danger of the spray—or even drift from it—touching cultivated plants near by, as, for instance, on grass paths in a rose garden, then a wax bar impregnated with a hormone can be lightly drawn over the turf. Such bars are available at a reasonable price under the trade name "Wonderweeder."

Some weeds are resistant to normal doses of hormones and need special treatment. These are mostly mat-forming plants of low-growing habit which are not cut off by mowing. Typical examples include clover, moss of various sorts, pearlwort, speedwell, and yarrow. Here, the main control must be in the use of lawn sand, and a good mixture can be made up as required with:

3 parts of sulphate of ammonia.
1 part of calcined sulphate of iron.

Application to patches of the weed should be made when the turf is damp and there is the prospect of fine weather; if a period of drought follows an application, then water should be applied to avoid serious scorching. Repeat the treatment as necessary throughout the growing season. Linked with this "spot" treatment, the growth of grass must be encouraged, as this will tend to smother low-growing weeds. Thus, in the early spring when the turf is wet, feed with a mixture of equal parts of superphosphate and sulphate of ammonia at 1 oz. per sq. yd. over the whole area and repeat after a month, if desirable. In addition, do *not* shave off the grass by close cutting; instead, the blades of the mower should be set as high as possible for a whole season.

Ponds.—Problems of weed control in ornamental ponds are often not easy to solve. Where duckweed is prevalent this small floating plant can be eliminated by sweeping the surface of the water at regular intervals. If this practice is carried out thoroughly much of the vegetative growth will be eliminated, and the plant will not be able to form resting bodies whereby it overwinters. Once a control has been established, further spread of the plant can be prevented by introducing a few moorhens or ornamental ducks.

The most common of unwanted plants in pools is blanket weed. There is no single means of dealing with this plant, for its spread is governed, to a certain extent, by unbalanced plant and animal life in the water. With this fact in mind, water lilies should be established so that their foliage shades about 25% of the water. In addition, a few oxygenating plants should be introduced from ponds or streams and a supply of gold fish added. Blanket weed is usually found in pools where the water gets overheated in summer; for this reason, the average depth of garden ponds should be a minimum of 18 in. and preferably a minimum of 2 ft.

Large Expanse of Water.—It sometimes happens that aquatic plants with large floating leaves, such as water lilies, get out of hand. Here, control can be established by cutting off the foliage with a long-handled appliance like the "Corypu Water Scythe." The work should be done early in June and repeated as often as any fresh growth is seen. Bulrushes are difficult to eliminate, but can be destroyed by digging out the roots when the level of the water permits. "Dalapon" has been found to give a control. Application should be made, with a wetting agent added, when the rush reaches maturity.

SPECIAL PROBLEMS OF WEED CONTROL.

Bindweed is to be found in most gardens. Up to the present time the main control has been to carefully fork out the roots as new growth is seen; if this is done methodically the plant can be eliminated within a reasonable time. Lately, chemicals have come to the fore, and bindweed may now be eliminated by watering or painting the foliage with a formulation of 2,4-D when the annual growth has nearly reached maturity. Thus, first applications can be applied in July and the treatment repeated as necessary to good effect.

DUCKWEEDS—In limited numbers these make good oxygenating plants; in quantity they become a great nuisance. Controlled by methodical sweeping or introduction of ducks. *Top*, Ivy-leaved duckweed. *Below*, Lesser duckweed.

Bracken.—Horticulturally, control is not a big problem, and in limited places it is easily dealt with by repeatedly cutting the aerial stems with a grass hook as the first frond opens. This practice will exhaust the underground food supply of the plant, and gradually it will die out. The young fronds are rich in plant food and, while still green and fresh, they should be composted. No chemicals will offer a reasonable control of this plant and, indeed, it is best dealt with by cutting and final digging out of the roots.

Couch Grass.—Where the soil is light and tends to be low in fertility, it is often found that this is a difficult plant to eradicate. If the long, underground stems are forked out in the conventional manner and left on the surface to dry the roots may be composted to advantage and a good control established. To prevent reinfestation, manures and fertilisers should be applied generously and the ground kept hoed regularly. See note on **Cultivated Ground.**

Ground Elder.—Without question this is one of the worst garden weeds and, whether or not the fact is pleasant or acceptable, it is indubitably a weed of neglected ground. In varying degrees it is resistant to hormone weed-killers of all sorts. On ground free of crops it may be reduced by an application of sodium chlorate, as explained in the paragraph **Open Ground.** The first application

should be made as soon as growth starts in the spring and repeated if the desired effect is not abundantly clear. When ground elder is to be found among herbaceous plants they must be lifted out and the weed removed by repeated hand-forking. In shrubberies reasonable control can be had by smothering the young growth in the spring with a thick dressing of peat, leaf mould, baled straw, or sawdust. If growth penetrates the surface dressing it will be found that the etiolated shoots are not difficult to remove by hand, or a second layer can be applied to complete the treatment.

Horsetail.—This is sometimes erroneously called mare's-tail and on poor, sandy soils it is often a common weed. Fortunately, recent experiments have proved that it can be easily controlled by spraying or painting the mature growths with a formulation of 2,4-D, taking care, of course, to keep the spray off cultivated plants near by. As the appearance of horsetail is symptomatic of low fertility, manurial treatment should be carried out on a generous scale.

Perennial Nettle.—Although this is a common weed, it is easily eradicated by thoroughly watering the foliage in the spring with a solution of a hormone like 2,4-D or, preferably, 2,4,5-T. This treatment should be repeated once or twice until the plants are eliminated. Isolated clumps can be dealt with by repeated cutting of young growth with a grass hook. The annual nettle is controlled by regular hoeing throughout the summer months.

Oxalis.—Of all weeds this is probably the most difficult to destroy. It is easily identified by its large, trifoliolate leaves like that of clover. Unlike other weeds, oxalis cannot be efficiently removed by hand, as this disturbs the bulbils clustered around the base of the stem of mature plants. On ground free of crops, sodium chlorate can be applied in March (see paragraph on **Open Ground**). Perhaps a second application may be necessary, but, even so, control may not be complete. Among shrubby plants, it may be possible to eradicate the weed by smothering, as suggested in the paragraph on ground elder.

Woody Plants.—These may be killed with 2,4,5-T. This hormone is particularly useful on bramble, gorse, ivy, and other unwanted shrubby plants. It is necessary to thoroughly saturate the foliage of deciduous trees, and the best results are obtainable when the leaves are fully mature but not starting to die off. In the case of ivy, the dormant shoots should be generously sprayed for the best results.

To sum up, there are many, many aids for eradicating weeds. The important point is to get the *right* method for *each* plant. Equally important is it to check on the reason why certain weeds grow profusely under some conditions, and to counter this natural tendency by appropriate cultural treatment, such as in the application of manures where horsetail is to be found.

HORTICULTURAL SOCIETIES.

There are many specialist societies in Britain. Detailed information on particular plants is normally available from them, and membership is open to all wishing to join. The most prominent societies are:

Alpine Garden Society

Sec. C. B. Saunders, Husseys, Green Street Green, Farnborough, Kent.

Auricula and Primula Society, The National

Sec. G. Redvers Williams, Mount Pleasant, Eastbury, Newbury, Berks.

Cactus and Succulent Society of Great Britain

Sec. K. H. Walden, 152 Ardgowan Road, Catford, London, S.E.6.

Carnation Society, The British National

Sec. R. K. Dowdall, 83 Woodward Road, London, S.E.22.

Chrysanthemum Society, The National

Sec. S. G. Gosling, 65 St. Margaret's Avenue, Whetstone, London, N.20.

Daffodil Society, The Midland

Sec. J. H. White, 76 Windyridge Road, Walmley, Sutton Coldfield, Warwickshire.

Dahlia Society, The National

Sec. H. F. Newson, 93 Byng Road, High Barnet, Herts.

Delphinium Society, The

Sec. C. J. H. Topping, B.A., Ph.D., Spark Lane, Sevenoaks, Kent.

Floral Decoration Society, The London

Sec. Miss Edith Hembley Parker, Top Hill, Great Goddesden, Hemel Hempstead, Herts.

Fuchsia Society, The British

Sec. B. W. Rawlins, 256 Great West Road, Heston, Middx.

Geranium Society, The

Sec. D. Martin-Roberts, M.A., 124 Argyle Road, Ealing, London, W.13.

Gladiolus Society, The British

Sec. R. H. Jeffers, 147 Wood Street, Chelmsford, Essex.

Iris Society, The British

Sec. Mrs. E. G. Osborn, 144 Ellison Road, Streatham, London, S.W.16.

Pansy and Viola Society, The North of England

Sec. F. C. Marsland, 2 Jubilee Mount, West Lillands, Brighouse, Yorks.

Pansy and Viola Society, The Scottish

Sec Hugh Campbell, O.B.E., 960 Dalmuir Road, Clydebank, Glasgow.

Pteridological Society, The British

Sec. The Rev. E. A. Elliot, South Stoke Vicarage, Nr. Reading, Berks.

Rose Society, The National

Sec. H. Edland, 117, Victoria Street, London, S.W.1.

Royal Horticultural Society, The

Sec. A. Simmonds, O.B.E., M.C., V.M.H., Royal Horticultural Society's Offices, Vincent Square, London, S.W.1.

Royal Caldeonian Horticultural Society

Sec. John Turnbull, D.S.O., D.F.C., C.A., Royal Caledonian Horticultural Society, 44 Melville Street, Edinburgh 3.

Houseplant Society, The Saintpaulia and

Sec. Mrs. D. Rudland, 11 Hanover Square, London, W.1.

Scottish Rock Garden Club

Sec. Sqdn-Ldr. J. J. Boyd-Harvey, Boonslie, Dirleton, East Lothian.

Sweet Pea Society, The National

Sec. R. J. Huntley, Broadland, 104 Uxbridge Road, Slough, Bucks.

THE GARDEN CALENDAR.

January.—All digging should be finished this month. As the work is done, so generous applications of organic matter such as peat, compost, sewage sludge, leaf mould, animal manure, or a mixture of any of them, should be incorporated into the ground. On clay soils the physical condition can be improved by raking into the surface dressings of rough materials like screened ashes, road grit, or coarse sand.

Fork over ground between rows of fruit trees and in shrubberies and bury annual weeds; if land is not free of weeds in January it is unlikely to be so throughout the year.

A trench for runner beans can be made, the bottom forked over, a thick dressing of compost or kitchen waste added, and the soil replaced.

Rhubarb will require protection with compost or straw and early growth forced by covering with small tubs.

GROUND ELDER—A pernicious weed of neglected land. Best eradicated by methodical hand-forking early in the year (*see* T33).

Pruning of orchard trees and fruit bushes should be completed. When bird damage is severe gooseberries can be left until bud burst.

Autumn-planted shrubs and trees should be checked over, and any which have worked loose through the action of frost or wind should be firmed by thoroughly stamping over the soil.

February.—Broad beans can be sown if conditions are favourable and shallots planted by pressing the bulbs into the soil until only the tips show.

Jerusalem artichokes are an unusual crop well worth growing; plant tubers as early as possible to give a long season for maturity.

Parsnips should be lifted to check new growth and stored on the north side of a wall or fence.

"Seed" potatoes can be arranged in boxes and kept in a frost-proof shed; a light, airy position will encourage short, sturdy shoots.

Protective covering on half-hardy shrubs, like fuchsias and mimosa, should be removed as early as possible.

Herbaceous plants which do not over winter easily, such as delphiniums and gaillardias, may be planted at the end of the month.

Turf may be laid in February so that the grass can be established before the ground starts to dry out in the spring. Before laying, rake in a dressing of "National Growmore" at 1½ oz. per sq. yd. to encourage root action.

Vines under glass should still be kept as *cold* as possible to maintain the dormant period. As the buds swell the temperature can be higher, but ventilation must be increased if it reaches 45° Fahrenheit.

Fuchsias grown under glass should be pruned hard by cutting back all of last season's growth to within a bud or two of the old stems. Later, as new growth appears, take cuttings which will root easily in sand under a plastic bag.

Shrubby plants like the india-rubber plant and most pot plants grown indoors or under glass should be repotted or top dressed with fresh potting compost.

Early strawberries can be obtained by cloching rows at the beginning of the month.

March.—Sow round-seeded spinach and broad beans for a succession in cropping.

Brussels sprouts, cabbage, lettuce, leeks, onions, parsley, parsnips, peas, and radish should all be sown as the soil gradually warms up.

Asparagus is easily raised from seed sown this month. Sow the seeds individually 1 in. apart and mark the rows by sowing a pinch or two of radish seed at intervals, as the asparagus is slow to germinate.

Onion sets can be planted as early as possible on well-manured ground.

Spring cabbage will respond in the spring to an application of nitrate of soda at 1 oz. per sq. yd.

Tomato seed may be sown in a warm greenhouse at the end of the month. It is a mistake to sow early in the year, as then seedlings get drawn and weak before it is time for planting outdoors.

Seed of half-hardy annuals, such as antirrhinums, China asters and *Phlox drummondii*, may all be sown in a greenhouse or frame. Remember the seed should only be covered with a sugaring of fine soil sufficient to "anchor" the seedlings and to sow thinly.

Hedges, and particularly evergreen sorts which have outgrown their stations, should be cut back, and this is the *best* month for doing so. Often drastic reduction is necessary, and such treatment will save endless, unnecessary work in trimming later on in the year. As an example, privet may be safely reduced to a width of 9 in. and a height of 4–5 ft.

Evergreen shrubs, like some daphnes, rhododendrons, and hollies, may be planted and—what is most important—kept moist until growing freely.

Over-grown lavender may be reduced in size by cutting back into old wood.

Lawns should be fed with fertilisers to encourage new, strong growth when the turf is damp.

As buds burst on roses, so pruning and manuring can be started.

Planting time for all fruit trees is nearly over, and should be completed without delay.

As buds burst on early planted raspberries, so the already shortened canes can be cut down to just above the lowest bud in growth; as further growth develops so the old stems can be shortened further until, finally, cut to ground level.

April.—Potato planting for an early crop is done this month using well-sprouted "seed." Protect from late frosts by covering the first shoots with earth and, if necessary, applying a coating of straw or sacking.

Onions raised under glass in boxes can be planted outdoors.

Watch for germination of asparagus seed; as the fern-like growths appear, hand weed the rows with great care and thin seedlings to 2–3 in. apart.

Hardy annuals can be sown outdoors when soil conditions are right; lightly cover and protect from birds. Half-hardy sorts must be grown-on in frames.

New stocks of carnations, chrysanthemums, and violas may be planted outdoors.

Transplant autumn-raised sweet peas to open garden early in the month.

Lawns may be sown as the soil warms up, and a good surface tilth can be obtained by raking; *prior* to sowing, make arrangements to protect the seed bed from birds by use of pea sticks, wire netting, strips of newspaper dipped into lime-wash, or "Glitterbangs" or a combination of these scarers.

Evergreen shrubs, like bamboos, hollies, and rhododendrons, should be planted and kept moist until well established.

Gladioli and montbretias can be planted in sunny positions where soil is in good heart.

Prune winter-flowering shrubs, such as winter jasmine and forsythia, by cutting off the old flowering stems.

Weeds will be appearing on garden paths and drives; establish an early and efficient control by watering with "Weedex."

Early planted fruit trees should be mulched with organic matter to conserve moisture in the soil.

May.—Brussels sprouts should be planted early in the month and also late potatoes. Watch out for blackfly on broad beans, as the first infestations are the important ones to deal with promptly.

Encourage growth on leafy vegetables, like lettuce and spinach, by a dressing of nitrate of soda at 1 oz. per sq. yd.

Towards the end of month plant out tomatoes, or in the first week if cloches are available.

Sow sweet corn and vegetable marrows in the open. Bedding plants and half-hardy annuals may all be planted outdoors.

Roses should be checked over for first signs of greenfly infestation; spray with nicotine if necessary.

Garden pools in need of cleaning should be dealt with thoroughly. At the same time water lilies may be lifted and divided when growth in the previous year was excessive.

Delphiniums now develop rapidly; for best results cut out thin shoots to leave five to seven strong growths to each plant. Stake and tie each one and encourage healthy growth by feeding with liquid animal manure or soot water on one or two occasions.

Faded blooms on azaleas, lilacs, and rhododendrons should be removed.

Agapanthuses and hydrangeas grown in tubs can be brought into a sunny position. If repotting has not been necessary remove top 2 in. of soil and replace with fresh compost. Encourage new growth with applications of liquid animal manure.

Window boxes should be repaired, filled with fresh compost, and replanted. Remember a generous layer of peat or leaf soil placed in the bottom will do much to conserve moisture.

Lawns will need attention, and broad-leaved weeds can be eliminated by treatment with hormone weed-killers.

Small greenhouses are liable to get very hot and plants suffer accordingly especially if short of water; therefore keep staging and floors well damped. Conversely, sharp falls in temperature may be experienced and everyday the ventilators should be shut down in the late afternoon in order to conserve the heat from the sun.

June.—Plant cabbages, cauliflower, celery, marrows, and tomatoes.

Sow seed of garden swedes.

After thinning beet, carrots, onions, and parsnips, feed with nitrate of soda at ½ oz. per yd. run.

Asparagus raised from seed must be kept clear of weeds and watered thoroughly at the least sign of being dry. Beds cropping in their third season should not be cut after June 1st; on old beds cutting may continue until the third week of June.

Sweet corn should be thinned and a surface dressing of compost applied.

Aubrietas now past their best should be clipped back hard to the old stems, with a pair of shears.

Seed of delphiniums, hollyhocks, lupins, and wallflowers may be sown.

Phloxes, especially if grown on light soil should be mulched with compost and watered when necessary.

Herbaceous plants of all sorts respond to feeding if growth is below par; individual species may be fed with soot water or large beds given an application of sulphate of ammonia at 1 oz. per sq. yd., taking care to keep the crystals off the foliage of plants.

Old flower-heads on roses should be removed regularly by cutting back old flowering stems to within 4 or 5 in. of the mature wood.

Raspberries and similar berries should be mulched with compost or old manure to encourage new growth.

Strawberries may be layered if the stock is healthy and growth vigorous.

July.—Plant winter cabbage, leeks, sprouting broccoli, and kales as ground becomes available

Sow prickly spinach and turnips for autumn and winter use.

Water celery, marrows, and runner beans at first sign of dryness. If setting is poor, beans should be sprayed vigorously with water from a hose.

Shallots may be lifted and dried off as foliage gradually yellows.

Carnations may be layered as sturdy young shoots develop; remove sufficient leaves to make a horizontal cut up the stem passing through a joint, and peg down.

Flag irises can be lifted and divided as flowering finishes. After replanting, the tubers should be showing above ground but, nevertheless, firmly in the soil.

Wallflowers may be lined out in nursery rows. To avoid sappy, lush growth do not plant on rich soil. Where ground is acid water plants with lime-water (a large handful to a gallon).

Hydrangeas can be easily propagated in July by cuttings of short flowerless shoots. These should be inserted in pots in a sandy compost and kept under a plastic bag or hand light until rooted.

Transplant into nursery rows, seedlings of biennials and perennials sown earlier in the year.

Order supplies of daffodils, hyacinths, and other bulbous plants for delivering in September. Stocks in good trade houses are often soon exhausted.

Late in the month hedges of beech, holly, hornbeam, and yew can be clipped.

August.—Runner beans are now in full bearing, and the pods should be gathered while still young, to encourage further croppings; often beans are picked much too old. Water and feed with nitro-chalk at 2 oz. per yd. run if necessary. If properly grown this is one of the most profitable of *all* crops.

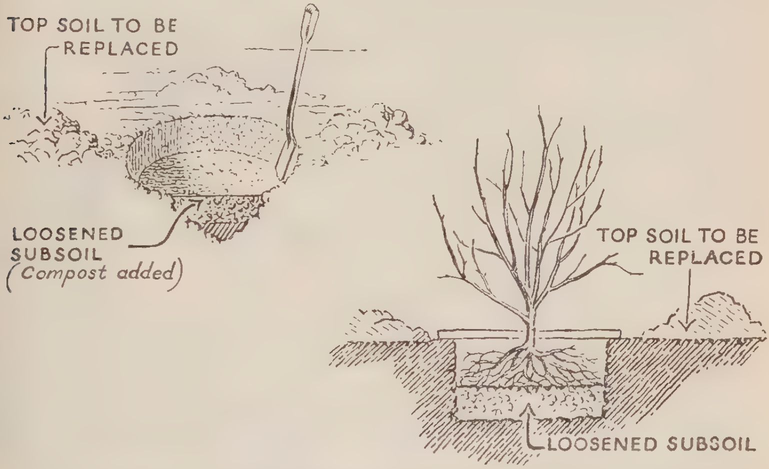
Marrows should also be gathered while still young and fresh; early development of seeds checks fruiting.

Strawberries layered in pots earlier in the year may be planted when the soil conditions are right. Use a well-manured site and plant at approved distances.

Raspberries and loganberries will now have finished cropping, and all the old fruiting canes may be cut out at ground level.

September.—Tomatoes can be gathered while still green and ripened easily and quickly by storing in open boxes, out of the direct sun, in a warm kitchen. Such a practice is better than putting the fruit in a dark, airless cupboard.

Ground recently cleared of onions and potatoes is admirable for planting out cabbages for spring cutting. Apart from removing any weeds, no preparation is desirable.



Correctly Planted Shrub, showing planting hole and bush in position. The loosened sub-soil must be firmed prior to planting, and any tree or shrub must never be planted deeper than it was in its previous position or nursery row.

Seed of prickly spinach—a valuable winter crop—may be sown. As seedlings develop, thin out and on acid soils apply lime-water.

Tomatoes should be sprayed with "Bouisol" at fortnightly intervals to prevent potato blight.

Winter greens, if not already planted, should be put in as soon as possible.

Pelargoniums ("Geraniums") should be propagated by cuttings taken throughout the month as young, short side-shoots develop. Rooting soon starts if the cuttings are inserted in sand or a mixture of sand and peat.

Border carnations may be layered; encourage rooting by not allowing the plants to suffer from a lack of water.

Madonna lilies may be planted this month in an open position where they will not be disturbed.

Flowering shrubs of a wide range may be propagated in August. Short side-shoots of the current season's growth should be taken off with a heel when the wood is still young but starting to harden at the base. Insert in sand and cover with a plastic bag.

Grass seed is best sown this month whenever the soil is moist but not wet, as in the notes for April. Before sowing, any perennial weeds must be removed by hand forking.

Brussel sprouts are heavy feeders and growth should be encouraged by an application of nitro-chalk at 1 oz. per sq. yd. early in the month.

Carnation layers will now be rooted and the young plants may be severed from the parents and transferred to their flowering positions.

Crocuses, daffodils, and snowdrops are often planted too late; September is the time for the job. Similarly, these, together with hyacinths, may all be planted in bowls for indoor decoration before the end of the month.

Lavender bushes can be trimmed when the flowers fade; do not, however, trim or cut back in any way the old stems or foliage.

Grass seed not sown last month should be put in without delay.

Roses of nearly every sort can be propagated by inserting cuttings 8–10 in. long in a shallow trench outdoors. A sprinkling of sand should be put in the bottom of the trench and the cuttings firmed well.

Brown rot is often prevalent on fruit. There is no remedy for the disease, and brown, rotten fruit on apple and other trees should be picked off and burnt.

October.—Jerusalem artichokes are safe left in the ground, but the stems should be cut down.

If a regular supply is wanted, then a store of tubers may be lifted to ensure against hard frost.

Parsnips may, similarly, be left in the ground until needed.

Asparagus stems should be cut down before the seeds drop. If "fern" is cut during the summer for indoor decoration, subsequent cropping is affected.

Lettuce for early cutting next spring should be sown, late in the month, under cloches.

Virgin ground which is to be taken into cultivation should be dug as soon as possible in order that it may be exposed to a *full* season of winter frosts. There is no doubt that the maximum value in digging virgin land can only be had if the work is completed well before Christmas.

Evergreen shrubs should be planted before the weather turns severely cold.

Lily-of-the-valley will respond to a top dressing of old animal manure or an application of bone meal at 2 oz. per sq. yd. followed by a mulch of leaf soil.

Clematis grown in pots may be planted in their permanent positions.

Lilies of various sorts can be planted early in the month.

Gladioli should be lifted, cleaned, and stored in a dry, frost-proof shed.

Polyanthuses and all sorts of primroses may be planted in moist, rich soil for flowering in the spring.

Sweet Williams and pansies may be transferred from nursery rows to their flowering positions.

Wallflowers should be planted without delay, firming the plants well. Forget-me-nots and daffodils may be used in conjunction with them and planted at the same time.

Most plants grown indoors have been watered freely during the summer; from now on care must be taken in applying water, as soil only dries out slowly in winter, and growth has virtually stopped.

Bulbs in bowls must be kept as cold as possible, and up to early November not more than about ½ in. of growth should be showing. Damp the peat as it shows signs of drying out.

Black and red currants and gooseberries may all be propagated by cuttings.

November.—Runner beans can be cleared and the haulms used for compost; the old roots can be left in the ground and later dug-in. If the sticks are pulled up early and stored they will last for some years.

Broad beans may be sown outdoors in districts where they are known to succeed; an allowance for losses should be made by sowing 3 in. apart.

Asparagus responds well to a top dressing of animal manure or compost; if supplies are short, aim to apply once in three years.

Lettuce sown last month under cloches can be transplanted and, under wide barn cloches, three rows can be grown easily for cutting in the spring. Slugs may cause serious losses, so water with "Slugit" at planting time and keep a few spare seedlings to fill any gaps.

Tulips may be planted throughout November.

Heaths and heathers of all sorts can be planted in peaty soils. Large clumps may be split up and replanted.

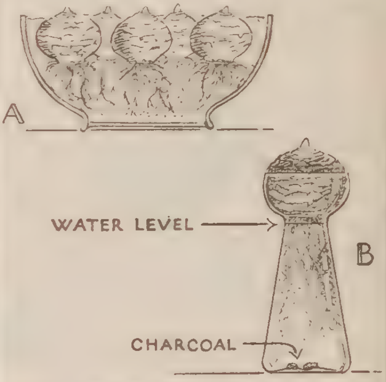
Roses and all deciduous shrubs and trees, including fruit trees of all sorts, should be planted as soon as possible. Always firm the soil well, but do not plant too deeply.

Where necessary, herbaceous borders can be replanted. Large clumps of perennials can be split up and the strong pieces from outside of the clump replanted; the centre of the clump should be discarded.

Continue to keep indoor bulbs as cold as possible. By the second week in November, growth should be about an inch high. Towards the end of the month, transfer to a cool, light position.

Throughout the winter continue digging and incorporating organic matter like compost, spent hops, and coffee grounds.

Vines grown in a cold greenhouse should be given full ventilation night and day. After leaf fall cut back annual growth to one bud.



Bulbs Indoors—Note strong root development before leaves appear. This factor can only be brought about by early planting (*see* September notes). In both bowl (A) and glass (B) a little bonfire charcoal is necessary for healthy growth.

December.—Decaying leaves on winter greens should be removed to give free circulation of air around the plants.

Bird damage may be prevalent on spring cabbages because of pigeons. In serious cases it is worthwhile to erect fish netting.

When frost makes cultivations impossible, pruning of fruit trees should be done. The only exception may be red currants and gooseberries, because in districts where bird damage is serious any pruning is best left until the spring.

Deciduous hedges of beech, hawthorn, and the like can all be cut back hard where the plants have got out of hand, with a view to reducing work of trimming during the growing season.

Well-berried holly is always in demand, and a variety of regular fruiting habit to fulfil the requirement is *Ilex aquifolium* 'Pyramidalis.'

For those wanting mistletoe, the seed should be planted on apple trees in the spring—not in December.

Early in the month, hyacinths can be brought into full light and warmth for Christmas flowering. If growth is a little stunted cover plants with a sheet of newspaper and give more warmth; if growth is poor look to the cultivator not the supplier.

Christmas trees to be brought indoors in pots should be thoroughly watered first, to check the needles falling through lack of moisture in hot stuffy rooms.

Care of Indoor Plants

By definition a house plant is one which can be permanently grown for decoration indoors. Such plants should not be confused with orchids, crotons, hibiscus, and the like, for these are really greenhouse plants or denizens of Scandinavian or American houses, where heat and air conditions may be automatically controlled. Conversely, the average British home is often cold and draughty, and has a high temperature in the evening and a very low one at night. This is far from satisfactory, but, in view of the fact, the cultivator of house plants must choose subjects tolerant of existing conditions.

Cultural Conditions.—Ideally, the temperature should be kept as constant as possible, and in cold weather plants grown in window-boxes are best moved nightly into the centre of the room to avoid damage by frost. Linked with temperature is the question of humidity, for plants respond well to a moist atmosphere. Here again the majority of rooms are ill-suited for growing plants. The condition can be improved, however, by sinking the pots in peat or wrapping them around with sphagnum moss. Alternatively, pots may be stood on a layer of gravel which can be kept damp without allowing water to seep through the bottom of the pot and thereby saturating the soil.

Other factors influence the health of plants indoors—gas fumes, for example, and draughts—so both must be avoided if possible. It will also be found that dust collects on the foliage, therefore plants with large leaves should be sponged regularly with soapy water. Others, with hairy leaves, like saintpaulia, may be gently sprayed, but the water must not be allowed to remain on the foliage, as it may lead to scorching or rotting.

Of all cultural practices, the most important is watering. Unfortunately, the right way and time to do this cannot be laid down emphatically, because the practice is essentially an art and not a science. As a general guide, plants may become *nearly* dry before watering and then be given a *thorough* soak by standing the pots up to their rims in a bucket of water. For all plants, rain-water is best; if tap water has to be used, it should reach the same temperature as that of the room before being applied.

Soils and Potting.—However well a plant has been grown, the turning point culturally is in its repotting, as from this juncture it either grows vigorously or soon declines. The important factor is to get the correct compost. This may vary slightly, but an all-round mixture can be made up of:

- 7 parts by loose bulk medium loam
- 3 parts by loose bulk granulated peat (or leaf soil)
- 2 parts by loose bulk coarse, gritty sand

This mixture is the basis of John Innes Potting Compost and, with fertilisers added, can be purchased in small quantities from horticultural sundriesmen. If fertilisers are not added, plants should be fed during the growing season at about fortnightly intervals (depending on the particular plant) with a dilute solution of liquid animal manure; alternatively, 2 oz. of the following mixture dissolved in a gallon of rain-water can be used:

- 5 parts by weight of sulphate of ammonia
- 7 parts by weight of superphosphate
- 2 parts by weight of sulphate of potash

Normally a plant will grow satisfactorily in the same soil for three or four years. After this annual growth may be poor, together with yellowing or dropping of the foliage. The plant is then in immediate need of repotting. To do this a large crock should be put into the bottom of the new pot—which should be generally a shade larger—followed by a little compost. Then the matted roots of the plant can be teased out with a pointed stick, put in the pot and more compost worked firmly around the roots. Some plants, of which palms are an example, prove intolerant of root damage, and repotting must be done with particular care, but, nevertheless, the compost must be made firm. When repotting is not absolutely necessary, the top inch of soil can be taken off annually and the pot top-dressed with fresh compost. Both repotting and top-dressing are best done before growth starts in the spring.

Propagation.—Many house plants are easy to propagate from cuttings or layered shoots. The former are taken off the parent plant at a joint in the stem by severing cleanly with a razor blade. After the lower leaves have been removed, the stems are inserted into a mixture of equal parts of sand and peat in a pot. A glass tumbler or specially-made, small, plastic tent is then placed over the top to avoid loss of moisture, and in a week or two rooting will have taken place. As for layering, this can be done by bending a shoot into a pot of sandy soil and pegging it down at a joint. When the layer has rooted it can be severed from the parent.

Health of Plants.—Fortunately the number of pests and diseases affecting indoor plants is small, and the large majority of troubles are due to faulty cultivation. Occasionally aphids (green or black flies) may be found on young growth, and can be destroyed by carefully wiping affected leaves and shoots with water containing a little detergent, repeating the practice if necessary. On ivies, in particular, sometimes a brown, waxy scale can be found. Underneath the protective scale is a small insect which sucks the sap, and without difficulty these can be removed by hand. Another insect occasionally seen is the mealy bug, an aphid which is surrounded by a prominent coating of a white, woolly substance; control in this case is to paint individuals with a dab of methylated spirits and to deal regularly with any reinfestation.

Basal rotting of flower stems and leaves, to be seen often on cyclamen and peperomias, is due to fungal infection, but this can be avoided by attention to correct watering and temperature. Similarly, premature yellowing of the foliage and leaf dropping is primarily a cultural trouble brought about by excessive cold, draughts, gas fumes, dryness, over-watering, perhaps over-feeding, or a combination of some of these factors.

SELECTION OF PLANTS FOR GROWING INDOORS

Florists' Plants

These are plants, like cyclamen and cinerarias, which are purchased in flower and usually discarded when flowering has finished, as their value lies only in providing temporary colour. Most of them are forced for seasonal trade in the moist atmosphere of a heated greenhouse, so do not respond kindly to treatment indoors.

One of the loveliest of these plants is *Azalea indica*, the Indian or evergreen azalea. After flowering it can be kept in a cool greenhouse. It needs plenty of moisture, and as it is a calcifuge, only rain-water can be used. To encourage growth after flowering, spray the foliage regularly and apply dilute, liquid animal manure or dilute soot water.

The most popular florists' flower is the cyclamen. It is difficult to grow really well, and cultural notes should be followed. With expert attention old plants can be flowered for ten years or more, although the best results are obtained from one-year seedlings. On the other hand, varieties of cineraria are grown as biennials. These need cool, airy conditions, and should be watered freely but, at the same time, with care not to over-water.

At Christmas-time numerous varieties of primula will be offered for sale. All of them are of comparatively easy culture, and if top-dressed and fed can be grown-on for a year or two. Some varieties, particularly those of *Primula obconica*, can cause a rash on those susceptible to it. Other plants which can be kept after flowering are the varieties of *Solanum capsicastrum*, the winter

cherry. It is a pleasing little subject and quite easy to grow. In season, the small, bushy plants are covered with large, red fruits and can be kept healthy by regular spraying of the foliage and attention to watering. When the fruit falls the young shoots can be trimmed back, the plant repotted and then grown-on in a cool greenhouse.

Indoor Plants

Unlike the florists' plants, those in this section are grown as permanent features of a house. The ones listed can be grown in most homes if given reasonable care, and all of them are available through normal trade channels.

Araucaria excelsa (Norfolk Island Pine).—Because of its likeness to a small fir tree, it is a plant to stand on its own. It is not difficult to grow if kept out of the full sun and the soil moist. One of the earliest plants adopted for growing indoors, but not often seen at present.

Begonia.—An enormous genus of plants of world-wide distribution, many being suitable for indoor cultivation. Of particular interest are *B. heracleifolia* and *B. manicata*, both being easy to propagate from cuttings under a tumbler.

Billbergia nutans.—This is a member of the pineapple family, the Bromeliads, having typically narrow, spiny-edged leaves. Nearly hardy, and will flower in a warm room. Do not repot unless absolutely necessary, as the roots are best confined.

Campanula isophylla (Harebell).—A charming blue-flowered plant with a long flowering period. Easily grown in cool conditions, and its pendulous habit makes it useful for a basket. After flowering, remove dead flower-heads and trim straggly shoots. There is a good white form, *alba*.

Cacti.—Innumerable sorts are used as house plants. In the main, all should be grown in a sandy, gritty soil with sharp drainage; water may be given freely in the summer, but withheld in winter, except to prevent the soil drying out. Two cacti which will flower freely and are particularly worthy of cultivation are *Aporocactus flagelliformis*, the rat's tail cactus, and *Epiphyllum ackermanii*. Both are tolerant of poor conditions and neglect. Mention should also be made of the old-fashioned Christmas cactus, *Schlumbergera bridgesii*, as a great favourite, but an infinitely more exciting one of a similar type is the rare *Rhipsalidopsis gaertneri* with bright-red flowers. These two are both easy to grow, and the latter was shown well at Chelsea in 1956.

Chlorophytum elatum.—Will tolerate a range of temperature and responds to occasional feeding in the summer. It is most attractive, with its green leaves striped with cream-coloured bands. A good plant for beginners.

Crassula.—Shrubby members of this genus make fine house plants, growing well in light soil in full sun. Particularly valuable are *C. lactea*—which has white flowers annually and large, succulent, spoon-shaped foliage—and *C. falcata*, a choice plant with red and yellow flowers.

Ferns.—Some will grow in rooms, but well-grown specimens of maidenhairs and the like are hallmarks of first-rate cultivation. Species of *Asplenium*, *Blechnum*, and *Nephrolepis* are worth trying. Compost is made up with equal parts of fibrous loam, peat, leafsoil, and coarse sand.

Ficus.—Species like *F. elastica decora* with broad, leathery, shiny leaves are often seen as window decoration in large stores. Not easy to grow in some circumstances; leaf-drop and yellowing may be caused by fluctuations in temperatures or draughts, and rain-water should be used when watering.

Helxine soleirolii (Mind-your-own-business).—Appropriately named from its habit of thriving where it is not wanted. Makes a pleasant mass of thin, green, trailing stems. Should be kept always on the wet side.

Ivy.—Common in many continental houses, for ivies show an interesting range of colour, shape, and size in their foliage. Invaluable as climbing plants and in warm rooms, the Canary Island ivy is worth trying. A related plant raised in France is *Fatshedera lizei*. All of these prefer a damp, leafy soil, and the foliage should be sprayed occasionally.

Monstera deliciosa.—A striking plant with large, deeply-cut leaves and long, thick, aerial roots, many of which do not reach the ground. Often seen as a prominent decorative feature of continental homes. Requires a leafy soil and generous watering. Spray or sponge foliage regularly and avoid fluctuation of temperature in its cultivation.

Nepeta hederacea variegata (Ground Ivy).—Creeping, hardy perennial native of Britain; variegated form makes an attractive addition to a hanging basket, having long stems and small kidney-shaped leaves. Correctly known botanically as *Glechoma* not *Nepeta*. Good plant for beginners.

Palms.—Like the aspidistra, the palm is considered a relic of Victorianism, and on such slender evidence is condemned on many counts. Notwithstanding, palms of various sizes make good decorative plants. Care must be taken when repotting, and for a number of years it is only necessary to top-dress provided that feeding is done in the summer. To keep the foliage green, the leaves should be sponged regularly or, better still, the plant taken out of doors and vigorously sprayed with water from a hose.

Pelargonium (Geranium).—Ease of cultivation and beauty are found in this plant and its infinite varieties. Some of these, like 'Mrs. Cox,' have multi-coloured leaves and are well worth hunting for in trade lists. During the summer feed generously and keep the stock vigorous by rooting cuttings annually in the late summer.

Philodendron.—Most climbing plants with aerial roots and represented by a number of species from tropical America. Fairly tolerant of adverse conditions, but dislike draughts and require light shade, free watering, and a rich, open soil. *P. scandens*, with heart-shaped leaves, is typical of the climbing group; *P. bipinnatifidum*, with broad, incised leaves, of the non-climbers.

Saintpaulia (African violet).—A charming, dwarf plant with hairy leaves and pretty single and double flowers in many colours. It is a *difficult* plant to grow well, as it thrives in a steady temperature of 65–70° F. and a wet atmosphere. Water from below. Rotting of leaves is due to excess of moisture, draughts, cold, or gas fumes.

Sansevieria trifasciata.—Perhaps unkindly but appropriately known as mother-in-law's tongue. It has a distinctive appearance, with stiff, erect leaves striped with gold. Keep warm and fairly dry; do not over-pot; tough.

Saxifraga sarmentosa.—Of easy culture and hardy out of doors; should be afforded a cool position and kept moist. Reddish leaves and pink flowers make it most attractive.

Tradescantia (Wandering Jew).—Tolerant of neglect and makes a fine trailing plant. For best results keep moist and feed during the summer. When green shoots appear on variagated forms these should be cut out at once.

Vines.—Two of these are particularly valuable as climbing plants; *Cissus antarctica*, kangaroo vine, is a native of Australia, and *Rhoicissus rhomboidea*, a Natalese plant which does not appear to have been grown to any extent in Britain until after the Second World War.

Zebrina pendula.—Related closely to *Tradescantia*, and often their nomenclature is confused. Like its relative, *Zebrina* is a difficult plant to kill. Its leaves have a pleasing metallic lustre, and beneath are a shade of blood-purple. Introduced from Mexico sometime before 1850.

Games and Recreations

Games and Recreations

INTRODUCTION.

The people of Britain have always been fond of spending their leisure hours in pursuits requiring physical effort or mental effort or both, and of thinking out special ways of celebrating special occasions. The result of this is a long history of games, recreations, and customs, some based vaguely on the pastimes of very ancient races, others appearing from time to time as the years and centuries passed; and, in a country with a strong sense of tradition, many activities of long ago still remain virtually unaltered, while many others retain much more than a trace of distant origins. For many years, most of the more highly organised pastimes were restricted to the nobility, but the ordinary people often contrived simplified or less formal versions of them, and always had plenty of recreations of their own. While the nobility took part in the joust that was the forerunner of fencing, the people took part in wrestling that remains wrestling; while the nobility enjoyed casting the bar that became throwing the hammer, the people enjoyed throwing the javelin that remains throwing the javelin; while the nobility performed masques and court dances, the people performed country dances, both sections of the populace thus playing their parts in paving the way for the theatre and the ballet.

About a century ago, games began to show more signs of organisation, with governing bodies coming into being to control them, and rules becoming fixed and codified. The object of these measures was to make the games available to more people, but the effects were, firstly, to make them more formal and less spontaneous, and secondly, to make the eventual classification of players of them according to ability at them inevitable. The next stage was probably equally inevitable. If you have classes you have a top class, and the top class is presumably worth watching. People began to spend the leisure time that had been used for playing games in watching others play them. This development began about seventy years ago, and reached its climax between the first and second world wars when not only games but also entertainments had multiplied and reached such high standards that they attracted as spectators those who, feeling that they were not good enough to participate, began to lose the desire to do so.

The second world war changed that, and started to swing the pendulum back again. It was a testing time that might have driven all thoughts of games and recreations out of people's minds, but it actually had the reverse effect. People needed recreational activities and entertainments as a relaxation, and a great many people were stationed in remote areas where, if they wanted these things, they had to provide them for themselves. Many, forced into a more active life than they had led for years, returned to games they had not played for years; and many, starved of entertainment, took to providing entertainments for their fellows. In many cases, the taste for these activities acquired during the war was retained after it, and it was helped and strengthened by various developments. On the one hand, there was a definite effort by certain associations and bodies to bring recreational activities, including some that had previously been the prerogative of the wealthy, within the reach of all, and to provide facilities and instruction in them; on the other hand, there was television. Television has been accused of restricting social activities by an ability to hypnotise people and keep them tied to their sets. It may well deserve some of these strictures, but there is also something to be said on the other side. It brings demonstrations of various activities to people who have never seen them before, and who, having seen them, often feel that they would like to try them; and, by bringing top-class sport to people's homes, often at times other than those normally used for outdoor recreation, it frees people who want to see the events from the necessity of giving up their own outdoor activities to watch them. This showing of major events at times more compatible with viewers' own recreational activities is achieved in two ways: one being the use of telefilms, and the other because of yet another post-war development, that of the playing of first-class fixtures in the evening by floodlight. Still another factor in the move back to practical, physical recreation is, of course, the increased leisure provided by shorter working hours. To-day, there are more people about than there ever were before; there is more spare time than there ever was before; and there are more recreational activities than there ever were before.

Any attempt at a thorough coverage of the present vast field of games and recreations in one section of this volume would be doomed to failure unless some limitations were applied. There is, therefore, no mention of sports in which the participant is largely dependent on mechanical aids, and none of racing, in which only a comparatively few people can actually take part as riders. There is, however, some mention of most sports and games popular in Britain, including fairly recent importations from abroad, and including also some overseas games that have not yet reached Britain. Indoor games are also included, though one section of them, card games, has had to be restricted to what might be called the major and most popular games of skill. Mention is also made of various non-competitive recreations, indoor and out; of children's games, again indoor and out; and of old games and customs in Britain and elsewhere, some of which survive to-day in whole or in part.

One problem that confronts those keen to try some game or recreation is how to set about it. In many cases, the simplest way of finding out what facilities exist in a particular area is to enquire at a local newspaper office, which will have particulars of all sports clubs, dramatic societies, and other recreational bodies in the area. A few addresses that might be useful to those with certain specialised interests appear at the appropriate places in the text, and a valuable source of helpful information on many games and recreations is the Central Council of Physical Recreation, which has English, Scottish, Welsh, and Northern Irish addresses as follows: England, 6 Bedford Square, London, W.C.1; Scotland, 4 Queensferry Street, Edinburgh, 2; Wales, 18 Windsor Place, Cardiff; and Northern Ireland, 45 Arthur Street, Belfast. Those keen on touring the country at moderate cost might appreciate the services provided by the Youth Hostels Association, which has addresses as follows: England and Wales, Trevelyan House, St. Albans, Herts, with a London office at 22 Gordon Square, London, W.C.1; Scotland, 7 Bruntsfield Crescent, Edinburgh, 10; Northern Ireland, 28 Bedford Street, Belfast; and the Irish Republic, 39 Mountjoy Square, Dublin.

American Football.

American Football is played eleven-aside on a pitch marked by a line across it every 5 yards, and with goals and a ball resembling those used in Rugby Football (*q.v.*), though the ball is smaller. Scoring is by "touchdowns," which are like Rugby tries, but count six; goals after touch-downs, which count one; field goals during play, which count three; and "safeties," which give the attacking side two points if the defenders carry the ball over their own goal-line and touch it down. The ball is advanced by carrying it, forward passing, and kicking. The game consists of a series of "plays" or "downs," the ball becoming dead when the ball-carrier is tackled. A team must advance 10 yards in four downs or give up the ball to their opponents. Players can run ahead of the ball-carrier to protect him by "blocking" opponents. Penalties take the form of distance, usually 5 or 15 yards, lost. A game lasts 60 minutes, divided into four 15-minute quarters.

Angling.

Angling, which is catching fish with rod, line, and hook, goes back to beyond the beginning of history, for it was known to the Greeks and Romans. It is now a recreation, for, though the catch may subsequently be cooked, it is not primarily fishing for the pot. It has its competitive side, with competitions offering prizes for the biggest catch, and there are angling clubs, but many people prefer to use it as a recreation to be enjoyed alone in quiet surroundings. It is actually not so much a recreation as many recreations, for fishing can take place in the sea, rivers, lakes, ponds, and even canals, and there are several entirely different kinds of angling. The most obvious divisions are fresh-water fishing, including coarse and fly-fishing, and sea angling, including fishing from piers and the shore and big-game fishing.

The biggest branch of angling is fresh-water fishing for general or "coarse" fish, which are so called to distinguish them from "game" fish like salmon. Coarse fishing is bait fishing, or, in the case of pike, spinning, groundbait also being thrown in before and during fishing. It covers many varieties of fish, and the bag may be a very mixed one. Certain fish, of course, are known to frequent certain localities or types of locality, but, though the angler may know exactly the kind of fish he is after, he rarely knows if his catch will consist entirely of that kind of fish, or even if it will include any of that kind. Coarse fish do not generally make good eating.

Fly-fishing for salmon and trout differ widely from coarse fishing, and from each other. As the name implies, artificial flies are used, but those used for trout are quite different from those that attract salmon. In the case of trout, a fly is made to resemble a real insect as closely as possible, but, with salmon, this is not necessary. Salmon rarely, if ever, feed in fresh water, and, when in that type of water, they are usually irritable. They will dart wildly at any objects that attract their attention, so salmon flies are simply bright objects designed to draw them on. Fly-fishing is rather an expensive sport, for it means hiring beats on private water. In both coarse and fly-fishing the angler would be well advised to keep out of sight of the quarry as much as possible.

Old though angling itself is, sea angling is a comparatively recent development of it, really dating back only to the nineties of the nineteenth century. It is now the most competitive form of angling, with sea-angling festivals and competitions plentiful during the holiday season. As with coarse fresh-water fishing, the catch can be a very mixed one. Sea angling has what might be called its equivalent of fly-fishing in fishing with feathers, which attract several kinds of fish.

The sea is also the scene of the greatest of all forms of fishing, big-game fishing, when a single bite can mean a catch of 1000 lb., if the angler can win the terrific battle to land it. Big-game fishing takes place from a motor-launch, which is not towed by the hooked fish, but follows it, so that the ensuing fight is between man and fish, and not between the fish and the dead weight of the boat. Such a fight could last for 12 hours, and it is never certain that the angler will win it. With fish of this size, some of them with a terrifying armoury of razor-sharp teeth, liable to turn back on the boat or leap clear of the water, big-game fishing can sometimes be as dangerous as the most adventurous sportsman could wish.

Archery. *See* **Old English Games and Customs.**

Association Football.

Games that may have resembled football were played by very ancient races, and games that certainly were football of a kind were played in the England of several centuries ago, but the Association Football that is the most popular game in Britain, and perhaps the world, to-day had its origins in the games played at English Public Schools in the days before sport became organised.

It was not surprising that some of those who had played football of one kind or another at school should want to go on playing after they left, but, before they could do so, it was necessary to work out a set of rules that would be universally understood and accepted. Meetings were organised by those interested, and, as the universities were natural meeting-places for boys from many schools, it was there, particularly Cambridge, that these took place.

It was soon evident that there was a major difference of opinion between those who wanted handling permitted and those who opposed this. The rival factions proved irreconcilable, so they went their separate ways. The handling enthusiasts based their rules on those in force at Rugby School, and thus pioneered Rugby Football (*q.v.*). Those who felt that football should be played primarily with the foot brought into being the game that was to take its name from the Association that was formed, in 1863, to govern it, and became Association Football, often called by the abbreviation, "Soccer."

Soccer is played with a round, leather-covered ball weighing from 14 to 16 ounces, and with a circumference of from 27 to 28 inches, on a pitch marked out as in the accompanying diagram. It is played eleven-aside, the positions being goal-keeper; right and left full-backs; right, centre, and left half-backs; and five forwards, playing at outside-right, inside-right, centre-forward, inside-left, and outside-left. The object is to score goals by putting the ball between uprights 8 yards apart and under a crossbar 8 feet high. The ball is advanced by kicking or heading, but only the goalkeeper when in his own penalty area may handle it, and he may not carry it. A game lasts for 90 minutes, divided into two halves.

The game is started by a kick-off from the centre, with all the opposing players outside the centre circle and in their own half. The ball must travel at least its own circumference into the opponents' half, and the kicker may not play it again until someone else has done so. The right to kick-off is decided by a toss that gives the winner the option of kicking or choosing which goal he will defend. Ends are changed at half-time, after which the ball is kicked-off by the side that did not do so at the start. The game is restarted in this way after each goal, the non-scorers kicking-off.

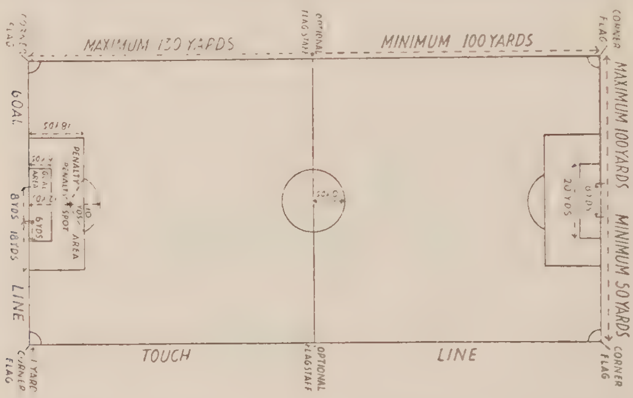
If the ball crosses the touch-line it is thrown in by a player of the side that did not put it out, the throw being two-handed. If it crosses the goal-line wide of the goal it is kicked-off by a defender from the 6-yards line if the attackers were responsible, and by an attacker from the intersection of the goal-line and the touch-line if the defenders were responsible.

Infringements are penalised by free kicks, which may be "direct" or "indirect." Direct free kicks, from which a goal may be scored, follow deliberate infringements, indirect free kicks, from which a goal cannot be scored, being for more technical offences. Offences by defenders in the penalty area are generally penalised by a penalty

kick, which is a shot from a spot 12 yards out from the centre of the goal, with only the kicker and the goalkeeper in the penalty area, and the goalkeeper barred from moving until the ball has been kicked. However, certain offences in the penalty area, such as carrying by the goalkeeper and obstruction, are penalised only by an indirect free kick.

A player is "offside"—called "sneaking" in the school games from which the rule came—if he is nearer the opponents' goal-line than is the ball unless there are two opponents between him and the goal-line, or unless the ball was last played by an opponent. He cannot, however, be offside in his own half, from a corner kick, or from a throw-in. If a player in an offside position interferes with the game, a free kick is awarded.

A game is controlled by a referee, who has the assistance of two linesmen. These may signal infringements, but the referee is not bound to act on such signals.



In Britain, soccer is a winter game, the season lasting from August until May, though, in Scotland, it continues even during the short summer season in the form of five-aside football, known as the "short" game. British soccer is highly organised, ranging from the fully professional Football League of four divisions and the equivalent, though slightly smaller, Scottish League through minor professional leagues to amateur leagues. There are also many cup competitions, from the Football Association Challenge Cup and the Scottish Cup downwards.

The game has also spread almost all over the world, being extraordinarily popular all over Europe and in South America, and played to some extent in the United States, Canada, South Africa, Australia, and other areas. There is a World Cup competition that is played for every four years, and an annual European Cup competition played for by the top club of almost every European country Soccer is also included in the Olympic Games.

Athletics.

The sport of Athletics, which includes running, walking, jumping, and throwing, is probably the most natural of all sports, and certainly one of the oldest, for it began in the days of pre-history or of mythology. Details of the Olympic Games of 776 B.C. are known, and it is certain that the Games were being held long before that. The story of Athletics is not, however, a continuous one, for the Romans discontinued the Games.

A later starting-point might be found in the country sports of various periods of English history, but, though these included some events that might be regarded as the ancestors of certain modern athletic events, they were mainly concerned with activities far removed from Athletics.

Modern Athletics probably really began in 1849, when the Royal Military Academy instituted a meeting that was followed by a similar meeting at Exeter College, Oxford, and, subsequently, at other Oxford and Cambridge Colleges. The Civil Service were also early in the field; and the first athletic club was the Mincing Lane Athletic Club, now the London Athletic Club. There was also the Amateur Athletic Club, which organised an annual championship meeting, and acted as a governing body for both athletics and amateur boxing.

In 1880 the Amateur Athletic Association was formed as a governing body. Other countries, particularly the United States, took to the sport, and in 1896 the first modern Olympic Games were held at Athens. Other international meetings and matches followed, and championships and competitions of all standards were started in many countries. Women came into the sport in the early 1920s, and were included in the Olympic Games in 1928. There is now a long list of internationally agreed standard events, including distances measured in yards and miles, and also their metric equivalents; and including also a major all-round test, the ten-event Decathlon.

The longest strictly standard distances are the Marathon of 26 miles 385 yards for runners, and 50,000 metres for walkers, but there are regularly held longer events. For runners, the longest annual race is between Durban and Maritzburg, about 55 miles, the longest in Britain being from London to Brighton, about 53 miles; but there are occasional 100-mile and 24-hour events. For walkers, there are annual 100-mile races and fairly regular 24-hour ones.

The Marathon is not, as might be expected, a revival of an ancient Greek race, for the Greeks had no races longer than 3 miles. It does, however, commemorate an ancient Greek event that is quite possibly no more than a legend: the supposed run by Pheidippides to take the news of the Battle of Marathon to Athens in 490 B.C. The first Marathon race, in 1896, was from Marathon to Athens, but the standard distance of the race is that of the 1908 Olympic Marathon from Windsor to the White City, London, which had just been held when it was thought advisable to have an exact standard distance. All Marathons commemorate the Battle of Marathon, but the oldest annual Marathon, the Boston Marathon, also commemorates the Battle of Lexington (the first battle of the American Revolution), and, more particularly, the ride by Paul Revere that preceded it.

Athletics is entirely an amateur sport. There are some professional races, but this side of the sport is called, not athletics, but pedestrianism.

There is a famous annual professional meeting at the Powderhall Grounds, Edinburgh, and there are other events in Scotland and the North of England. There are also professional meetings in Australia, chiefly in Victoria.

Cross-Country. Athletics is mainly a summer sport, but in cross-country running it has an extremely popular winter branch.

Cross-country originated in the traditional runs at various English Public Schools, particularly Rugby and Shrewsbury; and came into wider prominence when it was adopted by the Thames Rowing Club as winter training. It is still used as training by many sportsmen of all kinds, but it is now also a thriving competitive sport in its own right. There is an International Championship, but this is not yet fully representative, being virtually confined to Western European nations. Major cross-country championships are over courses of 9 or 10 miles.

Australian Football.

Australian Football is played eighteen-aside on large, oval grounds. There is no offside, and scoring in goals and behinds (near misses) is high. It is played to the practical exclusion of all other forms of football in the southern half of Australia.

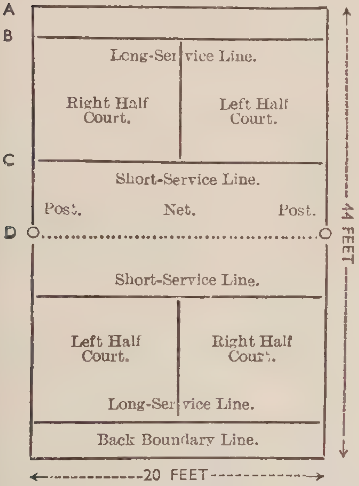
Badminton.

Badminton is said to have been invented by two guests at the Duke of Beaufort's house at Badminton in Gloucestershire, who spent a wet afternoon playing with the children's battledores and shuttlecocks. It seems certain that the game we know to-day did take shape at Badminton, from which it takes its name, but it is likely that its basis was a game originally played in the Orient.

Badminton might be described as an indoor version of Lawn Tennis (*q v*) in that it is played over a net, and can consist of either singles or doubles. There, however, the resemblance ceases. Scoring is by single points, and only the servers score, winning shorts by the receivers ending service sequences. The equipment used is lighter than that of Lawn Tennis, particularly the "shuttles" or "birds" that replace the ball. These are half-circles of cork in which feathers are fixed, and, as they do not bounce, all shots are volleys. Unlike Lawn Tennis, shots are made with the wrist, rather than the whole arm.

It is often said that it is impossible to play both Lawn Tennis and Badminton well, but this is not really true. Though the techniques differ, the eye for the moving object is the main requisite of both games. Badminton is a winter game, and many Lawn Tennis players turn to it during that season.

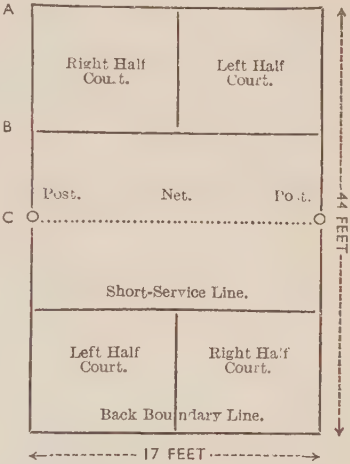
DOUBLES COURT.



NOTE.—If it is practicable place the posts on the side boundary lines; failing this, place them at any distance not more than 2 ft. outside these lines.

A to B 2 ft. 6 in. A to C 15 ft. 6 in.
A to D 22 ft.

SINGLES COURT.



NOTES.—Place the posts on the boundary lines or not more than 2 ft. outside these lines.

The back boundary lines become the long-service lines.

A to B 15 ft. 6 in. B to C 6 ft. 6 in.

Diagram of Ground as marked out for Badminton.

Ballroom Dancing.

Though the actual dances have changed from time to time, Ballroom Dancing has been one of the most popular of all recreations for a very long time; and while, in recent years, some other evening activities and entertainments have declined in popularity owing to the growing interest in television, the popularity of dancing has actually increased to a remarkable extent.

For many years, the "standard" ballroom dances have been the foxtrot, the quickstep, the waltz, and the tango; but these have frequently been augmented by various other dances, often novelty dances, that have been the subjects of sudden, and generally short-lived, crazes. A stronger challenge, however, has come from Latin America, which has exported quite a number of dances, most of them arousing some interest, and some of them winning and holding firm places. Many of them are ballroom versions of old native

and folk dances, which were often solo dances in their original form.

Dancing is highly organised, with its "governing body" composed of qualified teachers, and each dance has its recognised and approved fundamental steps and variations on those steps. If the popularity of a new dance justifies it, the authorities recognise it and approve step sequences. Many people dance regularly without ever having a dancing lesson, but, for the many others who really want to know all about the different dances and steps, there are countless dancing schools all over the country, where dancing is taught both in classes and in private lessons, and where special classes are arranged to teach any new dances that appear. These schools cater for absolute beginners absolutely regardless of age, and also for experienced dancers who want to rise to still higher standards.

A great many people dance purely for pleasure, and never think of dancing as a competitive activity. It is one, though; and there is a link between purely recreational dancing and competitive dancing in the system of medal tests. In these, dancers do not compete with other dancers, but simply try to achieve a certain standard. Beyond these tests, there are numerous competitions, ranging from local ones to world professional and amateur championships and international matches.

A fairly recent and very popular ballroom dancing innovation is formation dancing, in which teams consisting of a number of couples perform dances either as exhibitions or in competitions.

Old-Time Dancing. The most striking and, in some ways, surprising dancing development of recent years has been a tremendous increase in the popularity of Old-Time (often described as Old-Tyme) Dancing. A few old dances, such as the veleta, which, despite its name, is of English origin, had always retained at least a small place in dancing, but the organisation of dances in which every dance was of what might be called approximately veleta vintage was a new idea that seemed destined to enjoy at most the short-lived success that is the reward of novelties. That, however, was not the case. Interest in this type of dancing increased, and it has long since become firmly established, even to the extent of offering competitions. It is, in fact, no longer really true to describe it as old-time, for it is definitely part of the dancing of to-day.

This popularity is not, after all, so very surprising, for an old-time programme offers a wide variety of dances, most of them accompanied by exceptionally tuneful music. The dances are really similar to what, in some other countries, such as, for instance, Scotland, would be called country dancing, and include ordinary "pair" dances, sequence dances, progressive dances, and set or square dances. The veleta holds its place, as do several kinds of tango and many kinds of waltz, as well as the Canadian barn dance, the Boston two-step, the maxina, the lancers, and cotillions and quadrilles. Strangely enough, the cheerful Bohemian dance, the polka, is rarely seen. Old-time dancing provides no scope for just "walking round." The steps are in regular sequences, and all the dancers are making the same movements at the same time.

Bandy. *See* Skating.

Baseball.

The invention of Baseball, a summer game played from April until October, and the national game of the United States, is generally credited to an Army officer, its origins being old country games called "One Old Cat" and "Two Old Cat."

Teams are nine-aside, and bat and field in turn. The main part of the ground, the "diamond," has a "base," marked by a sack, at each corner, the lines from sack to sack being the "base paths." One base is "home," and there the batter stands, by a square of rubber on the ground, called the "plate." The base forward and to the right of a right-handed batter is "first," the one straight ahead of him is "second," and the one forward and to his left is "third," the distance from one base to the next being 30 yards. 20 yards out straight in front of the plate is the pitcher's "mound." The lines from home to first and from home to third are continued beyond these bases, and are the "foul lines."

It is the object of the batting side, using a bat which resembles a long, heavy Indian club with which to hit a hard, white ball weighing 5 ounces, to score runs, one being scored each time a player completes a circuit of the bases, not necessarily from one hit. When a batter leaves the plate, either "out" or to proceed along the base paths, the next man comes in, the team's innings lasting until three men are out. Nine such innings complete the game, and, in each innings, the batting side carries on at the point in the batting order reached in the previous innings. There is no toss for first innings, the visiting side always batting first.

The pitched ball reaches the batter without touching the ground, and, if not hit, it should pass over the plate between the batter's shoulders and knees. If it does so, it is a "strike," and three such strikes dismiss the batter. If it does not, it is a strike only if the batter swings at it; otherwise it is a "ball," and four balls give the batter a free passage to first base, called a "walk." A batter also walks if he is hit by a pitched ball. Other ways in which the batter can be dismissed are by being caught, and by being "put out" while on the base paths by failing to reach the base to which he is running before the ball. When an out is made, the ball does not become "dead." If there is more than one runner on the base paths, then, if the ball can be relayed quickly enough, two, or even three, men can be put out on the same "play."

If the batter hits fairly, he must run, but, to be fair, the hit must be in front of him and between the foul lines. A "foul hit" counts as a strike against him, except that the third strike, which actually dismisses him, must be a clean one across the plate. If a foul is caught, he is out.

The fielding side is divided into three sections, the "battery," the "infield," and the "outfield." The battery consists of the pitcher and the catcher, who stands behind the plate and gives signals indicating the kind of ball he thinks the pitcher should deliver: for, though the pitched ball does not touch the ground, pitchers can produce a wide variety of deliveries, including various kinds of curve. The infield consists of the first baseman, at or near first; the second baseman, between first and second; the shortstop, between second and third; and the third baseman, at or near third. The outfield covers the ground beyond the infield, the three remaining fielders taking the right, centre, and left sections of it. Catchers wear a large glove on the non-throwing hand, a mask, a chest protector, and leg-guards. All the other fielders wear a glove on the non-throwing hand, the first baseman's being larger than the others. The batter wears no protective gear.

Substitutes are permitted, pitchers frequently being changed if they are being hit, and "pinch hitters" being sent in instead of weak batters if a hit is desperately needed. If this happens, the man replaced, often the pitcher, cannot return when his side fields again, though his field replacement need not be the man who batted for him.

As with Cricket (*q.v.*) batting averages are recorded, these being calculated by dividing the number of times at bat into the number of hits. An average of 0·400, referred to as "four hundred," would be exceptionally good. "Hits" mean safe hits on which the batter achieved one or more bases without giving a chance. If he reaches base because a catch was dropped or a ball misfielded, he plays on from there in the usual way, but is not credited with a hit. Pitchers are graded according to the number of games won and lost. Recorded fielding statistics include each man's "put outs," "assists," which are throws from which a team-mate made a put out, and "errors."

In the United States there are clubs and leagues of all standards, from professionals of various classes through semi-professionals to amateurs, called "sandlotters," and boys. The top class of all consists of two major leagues, the National and the American, each with eight clubs. The champions of these two leagues meet in a best-of-seven-games series for the "Championship of the World," always known as the World Series.

Baseball is also the chief summer game of Canada, and it is quite widely played in some other countries, including Australia, Britain, and Japan.

Softball. Similar to Baseball is Softball, which is popular in the United States with girls as well as men, and which was demonstrated in Britain during the War by American and Canadian servicemen. The ball is not particularly soft, but it is larger than a baseball, and pitching is under-arm. Distances between bases, and between the plate and the mound, are shorter than in the parent game.

Basketball.

Basketball was invented by an American Y.M.C.A. official at Springfield, Massachusetts, as a winter team game that could be played indoors. It can be played in almost any gymnasium or hall, and it can also be played outdoors on an asphalt court. In America it is played by teams of all standards from schoolboys to professionals, and it is watched by more spectators than any other game. It has also spread to almost as many other countries as has Association Football (*q.v*), and it is included in the Olympic Games. It has been established for some years in Britain, where it has been encouraged by the Services and the Y.M.C.A.

Basketball is played five-aside, substitutes being permitted, with a ball resembling that used in Association Football, and goals consisting of posts that have iron rings with short nets attached to them and backboards. It is purely a handling game, and the ball is advanced by dribbling, which means bouncing, and by passing. Deliberate bodily contact is not allowed. Goals thrown during play count two points, and goals thrown from free throws after infringements one point. Height is an asset in the game, which demands stamina and agility, and which has been highly recommended as an ideal training activity by coaches of other sports, particularly Athletics (*q.v.*).

Girls also play Basketball in many countries, but not in Britain, where the nearest approach to it for women is Netball (*q.v.*).

Billiards.

Billiards, which originated in France, is a game of angles, and of very great skill. It is played on a table measuring 12 feet by 6 feet 1½ inches, having six pockets, one at each corner, and one in the middle of each side. The table is covered with green baize, the edges being of cloth-covered rubber, called "cushions." Across the table, 2 feet 5 inches from the bottom edge, is a line, called the "baulk" line, the space between the line and the bottom of the table being "baulk." On the baulk side of the line there is a semi-circle with a radius of 11½ inches from the centre of the line. Down the centre of the table are four "spots," one 12¾ inches from the top, one midway between the top and the centre, one in the centre, and one in the middle of the baulk line. Two white balls, one with a spot for identification purposes, and one red one, are used, the balls being played with "cues" that taper down to a striking tip. The remaining equipment includes a long, cue-like stick with a metal cross fixed diagonally on the end, called a "rest" or "jigger," and a special long cue, these being used when the player cannot reach his ball in the ordinary way. Most games are "singles," though "doubles" can be played, the object of the game being to score points according to fixed rules, an agreed number of points making the game.

To decide who is to start, players "string" by playing their balls simultaneously from baulk up to the top cushion, the ball which returns nearer to the bottom cushion winning. At the start, the red ball is "spotted" on the top spot, and players start from the baulk circle. Scoring is three for pocketing, or "potting," the red or going in off the red; two for potting the white, which is, of course, the opponent's ball, or going in off the white; and two for a cannon, which is hitting both the other balls. A player whose shot hits no other balls at all gives one point to his opponent, unless his ball goes into a pocket, when he forfeits three. A player's turn, called a "break," continues as long as he is actually scoring. When the red is potted, it is immediately respotted.

Snooker. Also played on a billiard table, and perhaps even more popular, is Snooker, which uses 22 balls, positioned as follows: 15 reds in the form of a triangle with its apex on the second spot from the top, and its base at the top end; a black on the top spot; a pink touching the apex ball of the triangle; a blue on the centre spot; a brown in the middle of the baulk line, with a green beside it on the left end of the baulk circle, and a yellow on the right end; and a white, which is the cue-ball to be played. The points values of the balls are from one for red, through yellow, green, brown, blue, and pink, to seven for black. A player's turn continues as long as he scores, his first shot being at a red, when, if he pots one, he plays at one of the other colours, play being at reds and colours alternately as long as balls are being potted, and as long as there are reds on the table, after which the remaining colours are played in ascending order of value.

Pool, Russian Pool, and Pyramids. Other games played on a billiard table include Pool, Russian Pool, and Pyramids. In Pool each player has a ball of a different colour, the order of play being white, red, yellow, green, brown, blue, pink, black. Each player plays at the ball of his predecessor, and tries to pot it, the game starting with white spotting his ball on the top spot, so that red is actually the first to play. A player whose ball is potted loses a life, players losing three lives dropping out of the game. A turn continues as long as a player is potting balls, and if he clears all the balls on the table he then spots his own ball for the next player.

Russian Pool uses the yellow, green, blue, and black balls, with the white as cue-ball, the black being placed on the top spot, the blue on the centre spot, the green on the left side of the baulk circle, and the yellow on the right side. A player's first shot must hit the black, after which he can play at will. Scoring is by potting balls, by going in off balls, and by cannons, but the black can be used only for the top pockets, the blue for the middle pockets, and the green and the yellow for the bottom pockets. Cannons count two, potting or going in off counting nine for the black, seven for the blue, five for the green, and three for the yellow. A player's turn continues as long as he is scoring, but consecutive cannons on the same balls are limited to 25, and the same ball must not be potted from the same spot more than three times in succession. A complete miss forfeits three points. A variation of Russian Pool adds the pink ball, which is spotted on the second spot from the top, counts six, and can be used with any pocket.

Pyramids uses the 15 reds, starting in their triangle, and a white cue-ball, the object being to pot the reds. A turn continues while a player is scoring, 8 balls potted ending the game.

Bird-watching.

Mention of Bird-watching might well bring thoughts of uncomfortable, and even hazardous, journeys to remote islands off the coast of Scotland, or at least to desolate parts of the Scottish

mainland; but, while it is true that expert bird-watchers of long experience do frequent these localities, as well, of course, as less-remote places like the Norfolk Broads, bird-watching can be practised, and should certainly be started, much nearer home, and with birds seen by almost everybody, though properly observed by very few, every day.

Bird-watching means exactly what it says: watching birds flying; watching two birds to see if they are, in fact, a pair, or if they are two males competing for the attentions of a hen-bird, which may be near by; watching where and how and with what materials they build nests; watching what they eat and how they get it; watching a pair in a nest to see if the male plays a full part in their domestic life, or if he just sits on a branch singing while the female does it all. If the bird-watcher really wants to increase his knowledge, and perhaps that of other people, careful observation accompanied by careful note-taking is essential, and will reveal some surprising facts. It has, for instance, been discovered that a pair of quite ordinary "garden" birds may fly sixty miles a day for every hundred yards their source of food is from the nest, and that the collecting of materials for building a nest may mean a total of six hundred miles flying. In time, the bird-watcher may wish to go in search of more unusual birds in remote places, but if he is anxious to increase the general knowledge of birds he might do better to remain close to his home; for, so keen have the experts been to track down the rarer birds, that far more is now known about them than is known about "ordinary" birds like the blackbird and the thrush.

Bird-watchers who would like to contact and compare notes with those with similar interests can do so by joining a Natural History Society, of which there is at least one in almost every county, full particulars generally being available at public libraries.

Boat Races.

Race rowing is a strenuous sport that makes no pretence of attracting as many active participants as some other sports and games; yet its long history includes races with unusual stories about them; races that are amongst the greatest annual international sporting events; and one race that provides what is probably the most enthusiastically supported free sporting spectacle in the world.

That, of course, is the Oxford and Cambridge University boat race, rowed on the Thames from Putney to Mortlake. First rowed in 1829, it has offered its excited public, which includes thousands of people with no connection of any kind with either university, everything, including runaway victories, dead heats, and even sinking boats. To all intents and purposes, this is a regular annual event, and has been so since 1856; but, in actual fact, every race is the result of a separate special challenge from the losers of the previous race to the winners of it. The race has an interesting parallel in the United States, where Yale University, whose colours are dark blue, annually meet Harvard University, which is at Cambridge, on a river called the Thames.

The Oxford and Cambridge race is the best-known annual race on the Putney-Mortlake stretch of the Thames, but it is by no means the only one. There are other races that attract entries sometimes numbered in hundreds: entries that are far too big to race abreast on the Thames, and so race in single file, with crews following each other at fixed intervals in what are known as the Head of the River races. The biggest of these is for crews of eight, but there are other Head of the River races for women's crews, who cover only part of this famous stretch of water, and for single scullers. Single scullers also cover this course in a straightforward race in the Wingfield Sculls event, which ranks as the English Amateur Championship, and which was first held one year after the first Oxford and Cambridge race, in 1830.

Head of the River races, but with a difference, are also held between the colleges of Oxford and Cambridge, where the Isis and the Cam, respectively, are much too narrow to permit straightforward racing. These are the Bump Races, in which each crew endeavours to catch and bump the crew ahead of it, except for the leading crew, which can concentrate on staying in front. When a bump is achieved, the two crews pull into the bank, and change places for the next day's racing. The racing goes on for four days, and it is, of course, the ambition of each crew, apart from the leaders, to register a bump on each day.

Back on the Thames, but farther down it towards the port and docks of London, is the scene of a race that makes the Oxford and Cambridge race and the Wingfield Sculls look like recent innovations. This is the annual race from London Bridge to Chelsea for the Doggett's Coat and Badge, a single sculling event open only to young watermen who are within twelve months of completing their apprenticeship. It was founded in 1715 in honour of the House of Hanover, and to commemorate the anniversary of "King George I's happy accession to the throne of Great Britain," by Thomas Doggett, a Dublin-born actor connected with the Drury Lane and Haymarket theatres, who regularly travelled on the Thames in preference to using the roads, and who left a sum of money to perpetuate the race, which is now controlled by the Fishmongers' Company.

This race is more truly an annual one than almost any other event; for, while most so-called annual races have been subjected to two long interruptions because of the First and Second World Wars, those qualified for the Doggett races during those years were subsequently traced, and the races duly decided after the wars. The event is a colourful one, for each race is followed by a barge carrying a batch of past winners wearing the Coat and Badge, and also the cap, breeches, silk stockings, and buckled shoes that go with them. The scarlet, pleated, quilted Coat, with its silver buttons, is worth £160, and the large silver arm Badge bearing the White Horse of Hanover and the word "Liberty" is worth another £20. They are presented at the Fishmongers' Hall, where the winner is greeted with a salute of trumpets and the tune, "See the Conquering Hero Comes."

For a rowing event of a very different kind, dating back "only" to 1839, one must go up the Thames, far beyond the end of the Tideway, to Henley, for the annual Royal Regatta. This consists of events open to the world and others closed to English colleges and schools for eights, fours without cox, pairs, double scullers, and single scullers, the most famous of its races being the Grand Challenge Cup for eights and the Diamond Sculls.

Finally, a journey far from the Thames and almost round the world will bring to light the story of a rowing trophy that first appeared sixteen years before Oxford first met Cambridge. The Carrow Cup was awarded for a four-oared race on the River Yare, in Norfolk, from Carrow Bridge to Whitlingham and back in 1813. Sometime during the 1840s that cup disappeared: to reappear in 1890—in Australia. In 1947 it came into the possession of the Victoria Rowing Association, which made it the trophy for a pair-oared race, but sent it to England in the Olympic year of 1948 for exhibition in the Olympic rowing museum. There it was recognised as a Norfolk trophy, and, though it returned to Victoria, it came home again in 1950, when the Melbourne club gave it to the Norwich Rowing Committee, which now annually awards it to "the Norwich club whose general performance, judged by a points system in Regattas, shall be best."

Bobsleigh Riding. *See* Winter Sports.

Bowls.

Bowls, one of the oldest of all games, was once regarded as "an old man's game," but it actually has many devotees of all ages and both sexes, and is played indoors as well as outdoors. It certainly goes back to the thirteenth century, when it

popularity made it one of the games legislated against as likely to draw people away from archery. Henry VIII played; and the famous game on Plymouth Hoe, in which Sir John Hawkins stayed to beat Sir Francis Drake even after the Armada had been sighted, if not definitely authenticated, is accepted as fact by several historians. It is interesting to note that, if this game was played, it would have been almost identical with a game of to-day, for it was in that century that the "bias" that is a leading feature of the bowls or "woods" was introduced. A century later, however, Bowls, which was largely played on greens attached to taverns, acquired a reputation as being merely an adjunct to pot-house revelry, but it was revived on a higher level in Scotland, and never again came so near to oblivion.

There are actually two games of Bowls, the Rink or Level Green game and the Crown Green game, and it is the rinks rather than the objectives that differ. The Level Green game is the more widely played, and it takes place on a perfectly flat piece of well-cared-for turf. The Crown Green game, which is popular in the North and Midlands, is played on a green of which the centre is 6 inches or more higher than the corners. The games differ—for instance, in the putting into play of the object ball—but only slightly, so it will be appreciated that the Crown Green game demands a good deal of experience and skill. It is mainly a singles game, whereas the Level Green game is played between sides consisting of one, two, three, or four players.

Bowls looks a simple game, the object being simply to place the bowls as near as possible to the object ball, or "jack." The bowls, however, are "biased," and the game is actually one of considerable skill. When bias was introduced, it took the form of weighting with lead, but it is now achieved by turning one side of the bowl less round than the other. Level Green bowls weigh up to 3½ lb., but Crown Green bowls are smaller and less biased. On the Crown Green, however, the jack, which is played into position by the first player, is also biased.

Players normally use two bowls in a game, or four in singles, and the side with the best record of bowls near the jack wins the "end," and the best record of shots in an agreed number of ends the game.

A Bowls green is such a perfect piece of grass that it might be thought that the expression "rub of the green," used to describe an unavoidable piece of bad luck, comes from this game. In actual fact, though, it would probably be more correct to attribute this phrase to Golf (*q.v.*).

Boxing.

Boxing, sometimes called "The Noble Art of Self Defence," though actually aggression is its keynote and defence an incidental, is a modern continuation of the old sport of prize-fighting, which, though always illegal, was popular from the time of the Regency until it was succeeded by the present-day glove-fighting at the end of the nineteenth century.

In prize-fighting bare fists were used, and wrestling holds were allowed. Rounds ended when a fighter went down, and fights continued until, following a knockdown, a man failed to come up to the scratch line in 30 seconds.

In modern boxing, gloves are worn, and no wrestling is allowed. Rounds last for a fixed time, generally 3 minutes with 1 minute between rounds, and fights last only for a fixed number of rounds, never more than fifteen. A knockdown does not end a round, the man who is down having 10 seconds in which to rise. If he fails to do so, his opponent wins by a knock-out. If a man fails to come up at the beginning of a round or if the fight is stopped to save a man from further injury, the victory is by a technical knock-out. If, however, both men are still on their feet at the end of the stipulated number of rounds, a decision is given on points. Boxing is therefore technically a contest of skill for points, and, as such, far removed from prize-fights to a finish.

Fights are controlled by a referee, and, in British professional boxing, he is solely responsible for any points decision. In amateur boxing the decision is given by several judges, who sit apart from each other. The difference between a good professional and a good amateur is probably more marked in boxing than in any other sport.

Boxing contests are arranged in classes according to weight, the divisions being: fly-weight, up to 8 stone; bantam-weight, up to 8 stone 6 lb.; feather-weight, up to 9 stone; light-weight, up to 9 stone 9 lb.; welter-weight, up to 10 stone 7 lb.; middle-weight, up to 11 stone 6 lb.; light-heavy or cruiser-weight, up to 12 stone 7 lb.; and heavy-weight, any weight. Amateurs have two additional classes, light-welter-weight, up to 10 stone, and light-middle-weight, up to 11 stone.

Prize-fighting was governed successively by "Broughton's Code," the "New Rules of the Ring," and the "London Rules." Then, in 1866, the eighth Marquess of Queensberry drew up the rules that have been the basis of boxing ever since. British professional boxing has been controlled since 1929 by the British Boxing Board of Control. The Amateur Boxing Association has governed amateur boxing since 1884, when it took over from the Amateur Athletic Club, which had looked after both boxing and athletics.

Prize-fighting is finished, but it has left a legacy, not only in modern boxing, but through an expression that has become part of the language, for the phrase "come up to scratch" originally referred to a prize-fighter stepping up for a new round.

Bridge.

Auction. Auction Bridge is a card game in which two partnerships of two oppose each other, each player facing his partner. A complete pack is used, the suits having special values, ranging from 6 points per trick for Clubs, through Diamonds, Hearts, and Spades, to 10 points per trick for No-trumps. When bidding, it is the points value of the bid, and not the number of tricks bid, that decides seniority, though the highest number of tricks prevails when the points values are equal. If a bid, or contract, is doubled or redoubled, the trick score is doubled or redoubled.

A player may pass, but, should he bid under the previous bid, he can be penalised, the player on his left having the option of closing the bidding at the previous bid or demanding that the offender make a proper bid. In this case, his partner is barred from bidding again unless the opponents do so. Should a player bid out of turn, the player on his left can demand a new deal.

Points are counted in two ways, below the line and above it. Points below count towards game (30 points), and are awarded for all tricks over six made by the contracting side. Points above the line are gained in various ways, and count in the final score, but not towards game. The first side to win two games wins the rubber, and 250 extra points above the line. The holding of honours also wins points above the line, as follows: three honours, twice the suit value; four, four times the suit value; five, five times the suit value; four in one hand, eight times the suit value, four in one hand and one in partner's, nine times the suit value; five in one hand, ten times the suit value. At No-trumps the honours count for Aces is 30 points for three, 40 for four, and 100 for four in one hand. The points for defeating a contract are 50 for each trick by which the contract fails. Extra points for making a doubled or redoubled contract are 50 for the contract plus 50 for each trick over when doubled, and 100 for the contract plus 100 for each trick over when redoubled. 50 points are awarded for a little slam, which is 12 tricks, and 100 for a grand slam, all 13 tricks.

The player who first named the contract suit is the declarer, and his partner is dummy. After the lead, which comes from the player on declarer's

left, dummy lays his hand face upwards on the table, and it is played by declarer, dummy having only limited rights of intervention. If his partner fails to follow suit, he can ask him if he has no cards in the appropriate suit; he can draw attention if too few or too many cards are played in a trick, or if the wrong side gathers up the trick; he can discuss questions of fact, and correct any claims made by the opponents to which they are not entitled. He cannot draw attention to any revoke; he cannot claim any penalty; and he cannot warn his partner against leading from the wrong hand.

Revoking is failing to follow suit when this is possible, the revoke becoming established when the player or his partner plays to the next trick. Up to then, the offender may correct it. The penalty is 2 tricks for the first revoke, and one for subsequent revokes, the penalty tricks to be taken only from the trick in which the revoke occured or later ones.

A lead from the wrong hand may not be withdrawn unless the opponents request this. If they do, the card is replaced, and play continues. If declarer's opponents lead from the wrong hand, declarer may either demand a lead in a particular suit from the right hand or reserve the right to have the exposed card played whenever he chooses to call for it. In this case, though, the offender may play the card before it is called, if he has an opportunity.

Contract. At Contract Bridge only the tricks contracted for are scored below the line, overtricks being recorded above it. The score for tricks is 30 in a major suit (Spades or Hearts) and 20 in a minor suit (Diamonds or Clubs). In No-trumps the first trick counts 40 and subsequent tricks 30. In bidding, the highest number of tricks prevails, regardless of suit values.

A game is 100 points, two games won constituting a rubber, which carries a bonus of 700 points, if the opponents have not won a game. In an unfinished rubber, a game gains 300 points and a part score 50, provided the opponents have no part score at all. A side winning a game becomes vulnerable, and this affects subsequent scoring.

Penalties for failing to make a contract are 50 points per undertrick if the declarer is not vulnerable and 100 points per undertrick if he is. If an opponent has doubled, the penalties are 100 for the first undertrick and 200 for subsequent ones if not vulnerable, and 200 for the first undertrick and 300 for subsequent ones if vulnerable. If the declarer has redoubled, these penalties are doubled. In successful contracts doubled, overtricks score 100 if declarer is not vulnerable and 200 if he is. A successful doubled or redoubled contract wins a bonus of 50 points. Bonuses are awarded for making slams, if they have been bid. If declarer is not vulnerable, the bonuses are 500 for a small slam (12 tricks) and 1000 for a grand slam (13 tricks). If vulnerable, the bonuses are 750 and 1500. Honours points are 100 for four honours in the contract suit in one hand; 150 for five honours in one hand; and, in No-trumps, 150 for four Aces in one hand.

A player making an insufficient bid may be required either to pass or to make a sufficient bid. If he passes or makes a sufficient bid in a different suit, his partner is barred from further bidding. A call out of turn is void, but, if it was a pass, the offender must pass in his turn, and, if it was not a pass, his partner is barred from further bidding. A player has no redress if he misunderstands a bid, though he can ask for a bid or a sequence of bids to be repeated. When three successive players have passed, the contract is fixed, declarer being the first player on the contracting side to nominate the suit, and dummy being his partner.

Dummy is entitled to ask for or give information on the laws, to point out revokes and try to prevent those about to occur, and to remind his partner from which hand he should lead. If, however, he looks at any hand other than his own, he forfeits these rights.

If declarer leads from the wrong hand the opponents can demand a lead from the correct hand; and, if it is possible, this must be in the same suit. If a defender leads when it is the declarer's turn, the card becomes a penalty card. If a defender leads when it is his partner's turn, declarer may either bar a lead in that suit or make the exposed card a penalty card. A penalty card must be played at the first legal opportunity.

Contract Bridge is a game of systems. There are systems for assessing the value of a hand, and there are more important and more involved systems governing bidding, the object of these being the interchange of information between partners.

Bumping Races. *See* **Boat Races.**

Camping.

For those whose holiday requirements are a maximum of fresh air and a minimum of formality, Camping is the ideal solution. Choice of equipment, such as tents, tent furniture, and cooking accessories, is entirely a matter for the camper, the only difficulty in this department being making a selection from the very wide variety available. The choice will, of course, depend to some extent on the type of camping holiday planned, for Camping can take several forms. It can, for instance, be static, or it can be combined with motoring, canoeing, cycling, or walking. The more static the camp or the heavier the transport, the more elaborate the equipment that can be taken, cyclists and walkers being restricted to the lightest, though not necessarily the least comfortable, gear.

Practically all suitable camp sites are privately owned, so permission to use them must, of course, be obtained. The choice of site is of major importance, and should combine proximity to water with shelter from winds. The pitching of the tent or tents is also important, as, if the campers intend to keep the tent " door " open at night, they will not want to face east, and be wakened unduly early by the rising sun. If the camp is static, tents should not be allowed to remain too long in one position, as this is not good for the ground on which they are pitched; and the hallmark of the experienced camper is that he leaves the site exactly as he found it. Rain is always a possibility, and demands certain precautions, particularly the slackening of the guy ropes, which might otherwise become taut enough to pull out the pegs, in which case the tent would probably be blown away. In wet weather the tent walls and roof should not be touched from the inside, as this tends to cause, or to reveal, leaks.

Several organisations exist to assist campers, including the Camping Club of Great Britain and Ireland, of 35 Old Kent Road, London, S.E.1, which specialises in lightweight camping, and has done much to develop suitable equipment and to obtain and list sites. There is also the Youth Camping Association, of 106 Ashurst Road, Cockfosters, Herts; and canoe-campers have an organisation of their own in the Canoe Camping Club, of 4 Felstead Road, Wanstead, London, E.11.

Canadian Football.

Canadian Football resembles American (*q.v.*) but is twelve-aside, uses only three downs, and limits blocking. Touchdowns count five.

Canoeing.

Canoeing is both a recreation and an organised competitive sport.

As a recreation, it can take the form either of simply taking a canoe out and " paddling about " for a short period or, by combining it with Camping (*q.v.*), of a lengthy and interesting river trip, the canoe-camper proceeding, of course, at his own pace, and giving as much time as he wishes to sightseeing.

As a sport, Canoeing has Olympic Games status. In Britain it has its headquarters on the Thames

at Teddington in Middlesex, the governing body being the Royal Canoe Club. There are races for singles and pairs, including events for women. There is also one long annual race for pairs that really combines Canoeing with Camping. The course is from Devizes in Wiltshire to London, and the competitors have to negotiate a long series of locks.

There are two types of canoe: Canadian canoes, like those used for many years by Red Indians, and kayaks, the very light Eskimo-type canoes, in which an expert, but not a beginner, can turn a complete circle into the water and out again without losing his seat in his craft. Both types are catered for in the Olympic Games, but all racing, and, indeed, virtually all Canoeing, in Britain is in kayaks.

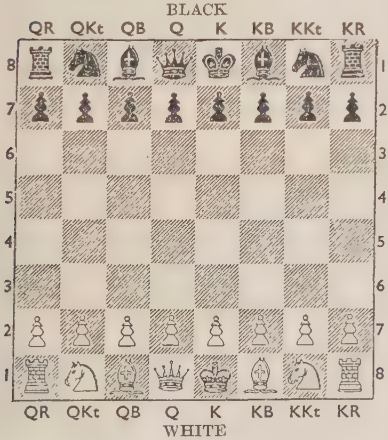
Card Games. *See* **Bridge; Patience; Solo Whist; Whist.**

Chess.

Chess, greatest of all board games and a game of pure skill, has a known history of some 1500 years. Eastern players, who originated it, reached a high standard, but the game's greatest advances were made in Italy in the fifteenth and sixteenth centuries. In the early days the value of the pieces and their moves underwent periodical changes, but the game we know to-day dates from the sixteenth century.

The board has 64 squares in eight rows of eight, and each player has 16 pieces, one set being white and the other black or red, but always referred to as black. A toss decides possession of white, which always starts. The object is the capture of the opponent's King, no matter how many pieces are lost in doing so, nor how many opposing pieces remain untaken. If the King could be captured on the next move, it is in "check." It must move out of check, and, if it cannot, it is "checkmate." and the game is over. If the King is not in check, but cannot move except into check, and the player has no other pieces he can move, it is "stalemate," and a draw. Games may also be drawn if neither player has sufficient pieces to force a win.

In addition to the King, each player has a Queen, two Bishops, two Rooks—sometimes wrongly called Castles—two Knights, and eight Pawns, and all these move in accordance with rigid rules. The following diagram shows the pieces at the start of a game:



(The initial position as seen by White)

Each line of squares across the board is a "rank," and each line up and down the board is a "file."

The permitted moves are as follows:—

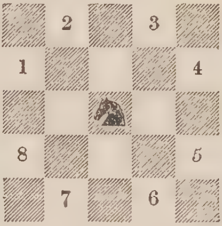
The King can move one square at a time in any direction.

The Queen can move in accordance with the powers described below for both Bishops and Rooks.

The Bishops move diagonally as many squares as desired.

The Rooks move straight along the ranks or files as far as desired.

The Knights move as shown in the following diagram:—



(The Knight's Move)

Stationed away from the side of the board, and on a black square, the Knight illustrated can move to any of the numbered white squares. The move is one square along rank or file in the desired direction, and one square diagonally. The Pawns move straight forward, one square at a time, but may move two squares when moved for the first time. They capture by moving one square diagonally forwards. A Pawn reaching the eighth rank may be replaced by any other piece.

Once during a game, a player may "Castle," by moving the King two squares towards the Rook, which is placed on the last square passed over by the King. This move cannot be made if either the King or any of the squares he would pass over are in check. Neither King nor Rook must have moved previously.

Games of Chess can be recorded, so players can play over great "Masters" games, and record their own games.

Draughts. Draughts—called Checkers in America—is also played on a chess board. Possibly older even than Chess, it is much simpler, but not devoid of skill.

Each player has twelve pieces or "men," all alike. Squares of one colour only are used, the men starting on the first three rows on the board. The move is one square diagonally forward, but a man reaching the eighth row becomes a "King," and may then move forward or backward. The object is the capture of all the opposing men by jumping over them. If the arrangement of the men permits it, more than one man may be captured in a single move. A man which can effect a capture but does not do so is removed from the board, or "huffed."

Children's Games.

Amongst the many sports and games that have come into being through the years and the centuries is a lengthy list of what, for lack of a more precise name, might be called Children's

Games, suitable for playgrounds or, indeed, practically any open space. Almost without exception, they are simple; they require little or no equipment; they can be adapted to almost any number of players; and they are good fun and good exercise. Most of them are also very old; few of them have any "official" name; and many of them have had many names

The "basic" playground game is Tag, in which one player, called "it," chases the others, any player he touches becoming "it." A variation of this allows players to rest without being tagged if they can find a piece of wood to touch; but there are many more variations that make more interesting games. In Imitation Tag "it" can follow any mode of progression he chooses, such as running, walking, running or walking backwards, hopping, or crawling on all fours; and whatever he does the other players must do, too. In Partner Tag all the players except "it" and one other stand about in pairs with their arms linked. "It" chases the other free player, who may link up with any pair, when the player at the other end of the link becomes "it's" quarry. For Chase Tag, all the players except "it" and one other form a circle, each player just touching his neighbour's shoulder with one outstretched arm. "It" and his quarry start at opposite sides of the circle, and the quarry may dive in and out under the outstretched arms, "it" being compelled to follow exactly the same route. A variation of this has three players running, with the second chasing the first, and the third chasing the second. Pursuit Race is a form of tag in which every player is both chaser and chased. Players station themselves in a very large circle, all facing either clockwise or anti-clockwise, and with approximately the same distance between each. At the word "Go," each player sets off after the one in front of him, tagged players dropping out.

Marching Tag also starts with the players in a circle facing clockwise or anti-clockwise, but they are close behind each other, and there is an "it" inside the circle. "It" announces a number, and then starts counting steadily up to it. As he does so, the others march round in their circle, but when he reaches the chosen number, they all dash away to a "home" line 25 or 30 yards away, with "it" in pursuit. Listen Tag starts with the players in a circle, facing inwards, and with "it" and one other player inside the circle. This other player announces a word, and then goes on talking or telling a story, in the middle of which he casually introduces the word. When he does so, the players dash for the home line, with "it" either in pursuit or calmly tagging some player who has missed the word and is still listening to the story. Numbers Tag has the players in two teams, who form rows, one behind the other, and both with their backs to the home line. The front team agree on a number that their rivals do not know, and a member of the rear team then calls out numbers in any order. If he hits on the agreed number, the front team swing round, each man trying to tag the man behind him before that player realises what is happening and dashes for the home line. Hidden Numbers Tag starts similarly, except that the teams face the home line, each player in the front team having a number that is unknown to the rear team. A player in the rear team calls out a number, and the player with that number dashes for the home line with the caller in pursuit. This goes on until everyone has gone, the last front-team player being allowed to run immediately his predecessor is either safe or tagged.

Bucket Tag has all the players in a line with their backs to the home line, "it," who is in the middle of the line, having a bucket several yards in front of him. He tries to toss a tennis ball or a rubber ball into the bucket, and the moment he succeeds, everyone dashes for the home line with "it" in pursuit. Ball Tag and Football Tag are like ordinary tag, except that, in ball tag, "it" must hit his quarry with a tennis ball or a rubber ball, which he throws, and in football tag he must hit him with a football, which he kicks. Another form of Ball Tag is between teams, and uses a football, which is thrown. The area is divided into two halves, one team being in each, and each half having an additional, narrow zone behind it. A non-player should act as referee, and start the game by throwing the ball up over the centre line, which no player must cross. The game consists of trying to hit opponents on the legs with the ball, any player who is hit retiring to the zone behind the other team, from where he can still take part in the game by throwing the ball at his opponents from behind if it should come through to him. The game continues until one half has been cleared. This "pitch" also serves for End to End Ball, in which half of each team starts off in the zone behind their opponents, and the ball is not thrown at opposing players, but through to team-mates behind the other team, each successful effort counting as a goal.

There are several popular "combat" games, in which players take part two at a time. Two are described, not very accurately, as Indian Wrestling. In one, the two opponents face each other, clasp their right hands, and press their right feet against each other, the "fight" consisting of an attempt to make the opponent move his foot by pushing with the clasped hand. In the other method opponents face each other, each with his hands pressed against his rival's shoulders, and with some object, such as an Indian club, a skittle, or even a stone bottle, on the ground between them, the object being to push the opponent in such a way that he will knock the object over. In Cock-Fighting two players with arms folded hop, each trying to make the other put his raised foot to the ground by pushing into him with his shoulder. Hat Snatch is more tag than combat, unless it is a combat of wits. Two teams face each other, some way apart, and having a hat or cap or some other suitable object on the ground between them. Each player has a number, the same numbers being used for both teams. A non-player acting as referee calls a number, and the players concerned, one from each team, try to snatch the object and carry it back to their own team, the one who does not get it trying to tag his opponent before he reaches safety.

Finally, three Tug-of-War variations. In Elbow Tug two players stand back to back with their elbows linked, each having in front of him a line, across which he tries to pull his opponent. In Rope Tug three players grasp a rope that has been tied so that it is actually a circle. The players are outside the circle of the rope, holding it with one hand, and having their backs to it. In front of each player is a small stick, which he tries to pick up, without letting go of the rope, before his rivals can pick up their sticks. Sprint Tug may end up as an ordinary tug-of-war, but it starts with the rope being placed at right angles across a line in the middle of the ground, and the two teams lined up at opposite ends of the ground. At the word "Go" they rush forward, the object being to pull the whole of the rope across to their side of the line. If this is not achieved before the other team arrives, it becomes a real tug-of-war.

Cricket.

Cricket, traditionally England's national game, has a longer history than most team games. There have been attempts to trace its origin in various games played by ancient races; and, even if some of these derivations are a little far-fetched, it certainly developed from very old country games, and has been played in a form not so very dissimilar from that of to-day for over 250 years. The men of Hampshire, particularly the village of Hambledon, Surrey and Kent were the real pioneers of the cricket of to-day.

Cricket is played by two teams of eleven players, which bat and field in turn. In the centre of the ground are two "wickets," 22 yards apart, and each consisting of three "stumps," joined at the top by two "bails." The bats used have a flat striking surface, and the ball is a hard red one weighing 5 ounces.

There is a batsman at each wicket, and their object is the scoring of runs by hitting the ball away, and running before it can be returned, each time the two batsmen cover the length of the

pitch counting as one run. Should the ball be hit beyond the boundary line round the ground, it counts four or, if it crosses the line without touching the ground, six.

The ball is "bowled" from one wicket to the batsman at the other, six balls, or, in some cases, eight, which comprise an "over," being bowled from each end in turn. The object of the fielding side is to get the batsmen "out," ten dismissals completing the "innings," as the eleventh man is left without a partner.

A batsman can be dismissed in several ways. If he misses the ball and it hits the wicket, or if he plays it on to the wicket, he is out "bowled." If he leaves his ground, indicated by a line in front of the wicket, misses the ball, and has the wicket "broken" by the wicket-keeper he is out "stumped." If he hits the wicket with his bat he is out "hit wicket." If his hit is caught he is out "caught." If, when running, he fails to reach his ground before the wicket is "broken" he is out "run out." If a ball, when bowled, would have hit his wicket, but hits his leg instead, then, subject to certain provisions regarding where the ball actually pitched, he is out "leg-before-wicket." A batsman may also be given out if he handles the ball or obstructs the fielding side, but these are rare occurrences.

In addition to runs hit by the batsmen, there are certain "extras." If the ball passes the bat, misses the wicket, and goes far enough for the batsmen to run, it is a "bye." If, however, it goes off the batsman's leg it is a "leg-bye," but leg-byes cannot be run unless the batsman was definitely attempting a stroke. If it is bowled so wide that the batsman cannot reach it, it is a "wide." If the bowler comes in front of his wicket before releasing the ball, or if he throws it, it is a "no-ball," in which case the umpire calls it as quickly as he can, for the batsman can hit such a ball, but he cannot be out to it, unless he is run out. If he does not score, one extra is added.

Of the fielding side, one, of course, is the bowler, and another, placed behind the batsman's wicket, is the wicket-keeper. The others will be placed as the bowler and his captain decide, for there are far more recognised positions than can be occupied at one time. To gain some idea of these positions, imagine a right-handed batsman at the wicket, his left side towards the bowler. The side of the wicket in front of him, nearer to his bat than to his body, is the "off" side; the side behind him, nearer to his body than to his bat, the "leg" side. On the off, behind the wicket and close to it, are the "slips," and, behind them, "third man." Farther round, but still behind the bat and close to it, is "gully." Level with the bat is "point" or, if he is some way from the bat, "deep point." In front of the bat, but in front also of the bowler's wicket, is "cover" and "extra cover." Roughly level with the bowler's wicket is "mid-off," with, behind him, "long off." Similarly on the leg side, where "long on" is the equivalent of "long off," "mid-on" of "mid-off," "mid-wicket" and "deep mid-wicket" of "cover" and "extra cover," "square leg" and "deep square leg" of "point" and "deep point," "short leg" of "gully," "long leg" of "third man," and "leg slip" of "slip."

First-class cricket matches last for three six-hour days or longer, but there are also two-day, one-day, and half-day matches. Matches of two days or more are two-innings games; of one day or half a day, one innings. If the side batting first, which is decided by a toss that gives the winner the choice of batting or fielding first, dismisses the opposing side for a smaller score, the victory is by the number of runs by which the smaller score was exceeded. If the side batting second pass the other total, the game ends, and the victory is by the number of wickets the second side still have standing. In a two-innings match, should the side batting first gain a first-innings lead of a certain size, normally 150 runs in a three-day match, it can require the other side to follow straight on with its second innings, the leading team keeping its second innings in reserve, to be played if needed. If a batting side has sufficient runs, and is anxious to see the other side batting while there is still plenty of time to dismiss it, it can declare its innings closed. In this case, should the second team score enough runs to win, it does, in fact, win, even though it may have lost more wickets than had the declaring side.

Cricket is not a fast-moving game, and for years views have been expressed to the effect that it must be "brightened up" if it is not to die out. Periodically, small changes in the rules are made; but, for the most part, the game just goes steadily on, easily retaining a large following that is satisfied with it as it is, and still able, when big international matches take place, to command a place, not only on the sports pages, but on the front pages of the Press.

The game is unusual in that it has no really official governing body. It is ruled by the M.C.C., which stands simply for Marylebone Cricket Club, from its headquarters at Lord's ground in London; and the M.C.C.'s pronouncements are accepted almost without question.

Outside England, the development of cricket has been peculiar. Even as near at hand as Scotland and Ireland, the game has never aroused much enthusiasm; and in Continental Europe, where many British games have won great acclaim, cricket has gained a real foothold only in the Netherlands. In the United States and Canada it is played, but only to a small extent. However, in the other Commonwealth countries of Australia, South Africa, New Zealand, the West Indies, India, and Pakistan, it is extremely popular; and the national teams of these countries, together with England, provide the top-class international sides of the game. They meet regularly in "Test Matches," a "rubber" normally being decided in a series of five Tests.

Cricket is rich in technical terms and expressions, which are seen and heard frequently through newspapers, television, and radio when a Test series is in progress. Many of these are almost self-explanatory, but a few never fail to puzzle less-experienced readers, viewers, and listeners. Prominent amongst these are three types of ball used by bowlers, the "yorker," the "googly," and the "chinaman."

A yorker is a fast ball that pitches just in the batsman's block-hole, and often passes under his defensive stroke. The term is believed to have originated in Yorkshire, but the only known explanation of it is that attributed to a Yorkshire cricketer, who, asked why a yorker was so called, replied simply, "Well, what else would you call it?" There is an answer to that, for the yorker was originally known as a "tice." A googly is an off-break or a leg-break which is disguised, because the bowler has delivered the one with the action of the other. A chinaman is an off-break bowled by a left-handed bowler to a right-handed batsman. These words also lack an authentic derivation.

Cricket has provided one expression that is now heard in many connections. That is "hat-trick," which dates back to the days when cricketers wore top-hats, and any player who took three wickets with three successive balls was presented with a white top-hat. Now, he is usually given the ball.

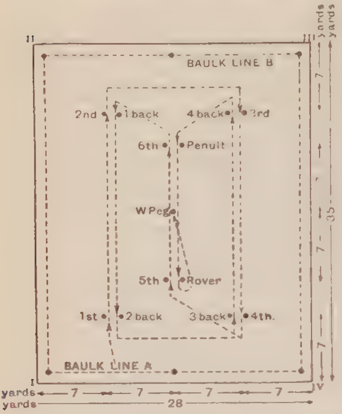
Croquet.

Croquet originated in France, and has been played in Britain for about a century. The governing body, the All-England Croquet Club was founded in 1868, with headquarters at Wimbledon. Soon afterwards, this also became the headquarters of Lawn-Tennis (*q.v.*), and it is probable that the rapid growth of that game was a factor that restricted the development of Croquet. Croquet, however, still retains a following, and, in addition to Championships and tournaments, it is widely played on private lawns.

The equipment consists of four balls, coloured blue, black, yellow, and red; four mallets, usually marked with the same colours; six hoops; and a peg. The playing area is 35 yards by 28 yards, but this can be reduced, provided that the proportion remains 5 to 4. The hoops, which stand 1

foot out of the ground, and the peg are placed as shown in the diagram. Generally two players, taking the blue and black balls, oppose two using

STANDARD SETTING.



Only those portions indicated by a continuous line need be marked on the court.

The order of making the points is indicated by the arrows.

the yellow and red, but singles can be played, each player using two balls, blue being paired with black, and yellow with red. Each player completes the circuit of hoops twice, finishing by hitting the peg.

Croquet is a game of skill, and players can earn extra turns in various ways, such as hitting another ball with their own or passing through hoops. While making their own circuits, players also concentrate on leaving their opponents at a disadvantage. Handicap matches are possible through the giving of extra turns, or " bisques." A " half-bisque " is an extra turn in which no hoop may be scored.

Croquet can, perhaps, claim some credit for a phrase used in everyday life. " Pegging out " has the rather sinister meaning of " dying " or " finishing," but it is actually the term used for finishing a Croquet round by hitting the peg.

Cross-country. *See* **Athletics.**

Cycling.

That few inventions have been so widely adopted so rapidly as the bicycle is not surprising, for this comparatively simple machine is at once a useful method of transport, a means of healthy and enjoyable recreation, and, for those who desire it, the " key " to participation in a thrilling and well-organised competitive sport.

The earliest cyclists aroused considerable hostility on the roads; but as cycling progressed through a series of unwieldy and dangerous machines to the present " safety " models, more and more people realised its many advantages, with few counterbalancing disadvantages, and it soon became established and accepted. A bicycle is not expensive, it should have a long life, and the riding of it is not difficult to learn.

From a utilitarian point of view alone, a bicycle can be extremely useful. A small amount of " luggage " can be carried, so it can be used for shopping, as well as for travelling to and from work, and for any necessary journey of reasonable length. Like walking, it provides exercise, but the cyclist can travel three or four times as fast as when walking. The rider is also independent of local transport services, while probably travelling, at least in towns, as fast as the public transport.

As a pleasant recreation, cycling offers a wide range of possibilities. Outings can be for a day or part of a day, or they can be tours of any length the rider wishes, with the overnight halts spent in hotels or hostels or Camping (*q.v.*), which can easily be combined with cycling. The cycle tourist has distinct advantages over both the walker and the motorist. The walker gets exercise and a good view of the country, but covers only a limited distance. The motorist covers plenty of ground, but sees little and gets no exercise. The cyclist, however, gets exercise while covering a distance which, if much less than the motorist's, is four times the walker's at a pace that still enables him to see the country, and spot places worth a stop for a closer investigation. Progress can be fast or slow, and exercise strenuous or leisurely, as the rider wishes.

As a competitive sport, cycling offers a remarkable variety, for no other form of racing provides events of so many different types. On the Continent, cycle racing is by far the most popular sport, and the leading riders are national heroes. The sport, which caters for both amateurs and professionals, also has a large following in Britain, where it would soon progress still farther if there were more tracks suitable for big events available.

Cycle races are held on banked tracks rather like motor-racing tracks, on flat grass tracks, on cinder tracks, on indoor banked board tracks, on roads, and even across country. There are races at all distances, from short sprints to road tours divided into daily stages lasting for several weeks. There are massed-start races, in which all the competitors start together; races in which competitors are drawn in twos or threes through several rounds up to a final; and time trials, in which each rider starts alone. Track races may be straightforward races or time trials; or motor-paced, with the riders behind motor-cycles; or tandem-paced; or pursuit races, with riders or teams of riders starting on opposite sides of or spaced round the track; or point-to-point, with points awarded to the leaders at the end of each lap; or courses des primes, with a prize for the leader at the end of each lap; or Madison races, for teams of two, and occasionally three, riding one at a time, and relieving each other at will. There are also races for tandems and tricycles; and the sport includes races on both track and road for women as well as men.

In the cross-country side of cycle racing, called Cyclo-Cross, riders cover a cross-country course of perhaps 10 miles, riding when they can and carrying their machines where riding is impossible. Still another form of cycle racing is roller racing. In this, the cycles are fixed on rollers, and do not move at all, the distance the riders pedal being registered on large dials. There is also cycle speedway, a sport devised by youths, and practised only by youths. Events take the form of team matches, generally on rough cinder tracks constructed on waste ground by the youths themselves, with pairs of riders opposing rival pairs in a series of races, and points awarded to the leaders in each race. Corners have to be " skidded " round, as they sometimes are in ordinary grass-track cycle racing. Very different, but still competitive in a way, is a form of event that provides a link between the sporting side of cycling and the more purely recreational side, the reliability trial or attempt to achieve a fixed standard.

Cycling also has its team game in Bicycle Polo, a hard game requiring a high level of cycling skill and considerable nerve.

Taking up cycling is simply a matter of purchasing a bicycle and devoting a short time to learning to ride it. After that, it is for the individual cyclist to decide for what purposes he wishes to use his machine, and whether he prefers to ride alone or in company. If he likes company there are many clubs which provide facilities for touring cyclists of all degrees of energy and ambition, as well as for racing cyclists.

There is also an organisation that caters especially for the distance tourist in the Cyclists

Touring Club, which keeps a check on premises offering accommodation to cycle tourists, and provides a sign for use on approved accommodation. It is interesting to note that the Automobile Association, which offers similar services to motorists, but which is not as long-established as the C.T.C., originally based its methods on those of the C.T.C. The C.T.C. address, for those who might be interested in joining, is 3 Craven Hill, London, W.2.

Dancing. *See* **Ballroom Dancing; Folk Dancing.**

Darts.

Originally just a casual amusement confined almost entirely to public-houses, the game of Darts is now one of Britain's most popular pastimes. Public-houses still provide facilities for it, but to-day clubs, canteens, factories, offices, and private houses also have their boards, and there are numerous team and individual competitions, including a National Championship. The prizes rival those of any other game for value, matches are widely reported, and the attendance for the bigger contests is limited only by the size of the hall. This enthusiasm is not misplaced, for the game is a test of skill, and luck plays little part in it.

The circular board has a diameter of 18 inches, and is divided into segments numbered from 1 to 20, but not consecutively. In addition, there are two rings, each ⅜ inch wide, that go right round the board and through each segment. These are the "double" ring, at the extremity of the board, and the "treble" ring, near the centre of the board, darts in these rings counting double or treble the value of the segment. In the centre of the board there are two small rings, the "bull" or "dosser," counting 50, and the "outer," counting 25. The bull is 5 feet 8 inches from the ground, and the wooden or metal feathered darts are thrown from a line, called the "hockey," 9 feet away.

Matches may be singles, doubles, or between teams of four or eight players. Games are for a certain number of points, usually 101, 201, 301, 501, 801 or 1001, the lower totals being used for individual, and the higher for team contests, and matches are generally the best two out of three games or "legs." Conditions for matches vary, but normally stipulate either "straight start and finish on a double" or "start and finish on a double." In the first case players score from the start, but in the second they do not score until one double has been registered. In both cases they must finish on a double, and they must finish with the exact number they require. Scores are counted downwards, players being told how many they need, rather than how many they have scored.

In addition to the straightforward game, there are many Darts variations. In one, "Round the Clock," a player has to throw one dart into each segment from 1 to either 20 or the bull, his turn continuing until he throws three darts unsuccessfully. In "Shanghai," players start with a complete throw of three darts at number 1, and continue with a throw at every number up to 9, but players who fail to score at number 5 drop out. In "Cricket," one player "bats," throwing normally, and counting everything over 40, while the other "bowls," throwing only at the bull, and counting one wicket for every "outer" and two for every "bull," five wickets ending his opponent's "innings." In a Darts version of Shove-Ha'penny players have to get three darts in each segment from 1 to 9, and three in the centre. In "Fives," players score only if their total is divisible by five.

Diving. *See* **Swimming.**

Dramatics.

For many years, "amateur theatricals" were a popular indoor pastime; but they were a recreation for the performers, offering little in the way of real entertainment to the spectators, and relying for their audiences on relatives and friends who had little option but to attend. In no sense were they either connected with or comparable to the professional stage.

There may still be a few "entertainments" of this kind, but the vast bulk of amateur drama to-day is something very different. It is something that is taken really seriously, that is worked at, and that can entertain a paying audience on its merits. Relatives and friends still attend, of course, but so do strangers in search of entertainment, many productions, particularly big musical ones, depending on public audiences to cover their heavy expenses. The change from light-heartedness to seriousness, and from play to work, far from driving performers to seek recreation elsewhere, has increased the popularity of this particular recreation to a phenomenal extent. Nobody can say with certainty how many amateur groups there are in Britain at any one time, for new ones are springing up all the time, but there are certainly thousands.

Surprising though it may seem, the amateur theatre movement made tremendous advances through the Services in the Second World War. There was a certain amount of professional entertainment available to servicemen, but, for much of the time, service units had to provide their own entertainment. In many cases a few enthusiasts who knew something about entertaining were found to start things moving, and these soon built up casts by "conscripting" those in whom they thought they saw talent, and, often with considerable ingenuity, staged some excellent shows under very difficult conditions. Many of those who were "forced" into amateur entertaining during those days remained in it after the War, and many of the things that producers of those shows had to teach themselves by experiment and trial and error have contributed to better productions since then.

People often query whether or not it is fair to judge amateur actors by a severe standard, or to compare them with professionals. Generally speaking, it is perfectly fair to do both. Though amateurs are acting voluntarily, and because they like it, they are, nevertheless, setting out to entertain audiences whom they charge for admission. This renders them liable to criticism, and most serious amateur performers would not want it otherwise. With regard to comparisons with professionals, amateurs cannot, of course, fairly be compared with the best professionals, but they can be compared with, say, professional repertory companies, and they should emerge from such comparisons with distinction. Professional repertory actors generally perform a different play every week, rehearsing each play while they are acting another, and rehearsing only for a short time. Amateurs usually rehearse for a long time, and with only one play to think about. They should, therefore, if they are of any standard at all, give a better performance than the harassed repertory players.

The connection between the professional and amateur stage to-day goes beyond the mere making of comparisons. Professional theatre people sometimes assist at summer and week-end schools for amateur actors, and many amateurs have helped out both repertory and touring companies by playing small parts and appearing as "supers." Many young amateurs, particularly in musical shows, hope that the amateur stage might prove the first step towards a professional career, and some amateur groups include former professionals who, for one reason or another, have left the theatre.

There are several ways in which the amateur theatre can be of real assistance to the theatre as a whole, particularly in that amateurs can try out new or experimental plays that the professional, commercial theatre dare not risk. Many amateur groups conduct vigorous and useful theatrical experiments, and this also applies to some musical groups. Other companies, both straight and musical, prefer to concentrate on proved successes.

The days when the first consideration in choosing a play was that it should have parts for every member of the group are gone. Groups now normally select plays on their merits, and often cast them, as in the professional theatre, by competitive audition. This, however, need not discourage those who might feel that, if parts have to be "won," they would never get any. Even these more ambitious groups often, in addition to their main plays, stage supplementary programmes consisting, perhaps, of three or four one-act plays, which are cast from those omitted from the bigger productions; while some groups definitely pick an occasional play, possibly a costume drama, that has a long cast. There are also plenty of small groups that often find themselves with too few people for the play they want to do. A newcomer can always find a welcome somewhere. Many amateurs start with small groups, and either remain with them or move farther up the tree, as their particular ambitions or talents may suggest.

There is also a vast field for enjoyable and useful activity behind the scenes. Many of those in the amateur theatre movement never appear on the stage at all, preferring to concentrate on producing, stage-managing, set designing, lighting, or one or other of many essential jobs; and anyone whose ambitions follow these lines is always welcome. Producing plays is, of course, an extremely important and satisfying activity. Small groups will often let a new producer try his hand, while the more ambitious groups will offer opportunities to new producers in the supplementary programmes which they also use to give newcomers acting opportunities.

Straight plays and musical comedies, comic operas or operettas are the best-known branches of the amateur theatre, but amateur revues are also frequently seen. Many of the improvised Services shows were of this type, and the taste for them has increased. They provide opportunities of many kinds, not only in singing, dancing, and acting, but also in composing, song-writing, and writing sketches. Still another type of amateur entertainment born during the War is the radio-style play, which was first tried in prisoner-of-war camps, when no other type of play was possible. In this, performers read their parts behind a curtain, submitting themselves to the severe test of holding their audiences by the voice alone.

One other branch of "home-made" entertainment that is not generally considered a part of the amateur theatre, but that is definitely worth a word, is skiffle. In its commercialised form skiffle became associated with, and almost indistinguishable from, the "rock 'n roll" craze, but it would be more correctly regarded as something that should be quite remote from "rock 'n roll," and remote also from periodical crazes. It might be described as the making of music by ordinary people, often with improvised instruments, and it probably had its origins in various times and places, where, had it not been for this type of music, there would have been no music at all. The music normally takes the form of songs, and these should really be descriptions of actual local, national, or world events, rather as the calypsos are. The songs may be old folk-songs, or up-to-date songs of the same type, set, perhaps, to old or existing tunes; and if skiffle groups would include in their repertoires modern descriptive songs of their own making they would add considerably to their own and their audience's entertainment.

Film-making. While it is not too difficult for amateurs to present their own plays, it might seem that amateur film-making, apart from purely private records of things like family holidays, is too ambitious a project to be seriously considered. This, however, is not the case; and if those whose ambitions are to act, direct, and write for films have fewer opportunities than their stage counterparts, they nevertheless have opportunities, and a growing number of them, in the various film societies, now more often called ciné clubs.

These clubs make their own films, including fiction films, documentaries, and cartoons, and many of them attract attention far beyond the club that made them. The clubs also show members films other than those made by themselves, including some made by other clubs; and they periodically entertain and visit other clubs.

Draughts. *See* Chess.

Eton Fives. *See* Fives.

Fencing.

Fencing can claim a longer history than most sports, for it is the modern equivalent of duelling. In mediæval tournaments mounted knights fought with lances, and, in addition to actual fights to the death, they also met with special, less lethal lances purely for sport. Later, duels were fought dismounted, and with different weapons. In Elizabethan days duellists used a sword, for attacking, in the right hand, and a dagger, for defence, in the left. Later still, the dagger was discarded, and duels were fought, as are fencing bouts to-day, with a sword only.

Duelling declined in Britain during the Regency period, when it became fashionable for gentlemen to learn to fight with their fists, but they continued to learn swordsmanship, and to fence with the practice weapon, the foil. Eventually, duelling became illegal almost throughout the world, but swordsmen of other countries similarly continued to fence with the foil. Even before Britain took to fist-fighting, most of the advances in fencing technique had been made in France and Italy, and the fencers of these and other Continental countries are still the best in the world, countries like Britain and the United States relying largely on fencers of Continental European descent.

Duelling was restricted to "gentlemen," and something of this restricted atmosphere pervaded the early days of fencing as a sport, clubs being few, expensive, and rather exclusive. Now, however, that has changed, and widespread class tuition in fencing has opened the sport to anyone.

Modern fencing includes contests with three weapons: the foil, which is the only one used by women; the epée, the real duelling sword; and the sabre, which cuts as well as thrusts. These weapons have "buttons" on the points, but fencers wear a special glove, a padded jacket, and a mask. Fencing requires grace of movement, lightness of foot, agility, strength of wrist and forearm, quick mental reactions, and good eyesight; and it will do much to develop these qualities, including the eyesight. As masks are worn, it is perfectly practicable to fence wearing glasses.

The language of fencing is French, all the terms used, many of them traditional, being French.

Film-making. *See* Dramatics.

Fives.

There are two games of Fives, Eton Fives and Rugby Fives. They are court games using walls, but an Eton Fives court has the addition of a buttress or "pepper" jutting out from one side wall. The striking implement is the gloved hand. Eton Fives is a doubles game, but both singles and doubles are played in Rugby Fives.

Folk Dancing.

From the ballet, by way of the less-serious stage and the ballroom, to country and folk dancing, there are many forms of dancing, and it is easy to trace links from one kind to another, but much harder to say definitely exactly where one kind stops and another starts. Of all types

of dancing, perhaps Folk Dancing is the most difficult to pinpoint. Its name implies that it would be found chiefly in remote areas, where it would be performed, almost instinctively, by simple country people. Originally, it was, and, to some extent, it still is; but it is now also to be seen in ballet and in the ballroom in adaptations that may or may not have retained the main features of the original, but that have almost certainly lost the spirit of it. To many people, thoughts of folk dancing mean thoughts of Central Europe; of places like Bohemia with its polkas. Central Europe, however, by no means covers the subject. Italy, for example, is rich in gay dances, and in dances with folk-lore-type stories behind them, like the famous tarantella, which is reputed to induce enough perspiration to cure the bite of the tarantula. Latin America, too, has its rumbas and other native dances that were originally solos, but are now known mainly in their ballroom versions.

There are good grounds for regarding the term "folk dancing" as nearly synonymous with country dancing; for if country dances differ, as they do, in different countries, they are not only countryside dances, but dances of a particular country, and therefore of its people. Almost every country has its country or folk dances, though it has been said that England is an exception. It is, however, nothing of the kind, for English Morris dancing has been a part of England, and of England's holiday festivals and customs, for centuries, and remains so to-day, about fifty different teams or groups now being affiliated to the Morris Ring of England.

The origins of Morris dancing, and even of its name, are shrouded in mysteries that will probably never now be solved. The name probably comes from the word "Moorish," and it was certainly used to mean Moorish by Shakespeare. Morris dancing, though, dates from long before Shakespeare's time, so, while the word may be the same as Moorish, it is probably used in the mediæval meaning of Moorish, which was simply "pagan." It may be, therefore, that Morris dancing was based on rituals of the old religion, and that the facial disguises that figure in it were originally necessary if the dancer was to avoid persecution and prosecution. A theory that Moorish was used in its more normal sense because the dancers blacked their faces falls down on the fact that only a minority of Morris dancers ever did this. To-day, only the Lancashire Coconut Dancers do so. For centuries, Morris dancing was mainly associated with England's May-day revels, but it was, and is, also seen at other times, such as for instance, Boxing Day.

There are many different Morris dances, including handkerchief dances; stick dances, using either 3-foot quarter-staves or seed-planting sticks of half that length; and jigs. Most of the dances are for teams of six, but some of the jigs are danced as solos. The accompaniment was originally on pipe and tabor, both being played by one man, but is now mostly on accordions and violins. The dancers are generally preceded by their Fool, armed with a stick and bladder, with which he clears a space for the dancing.

Scottish dancing is famous; but what is less generally realised is that there are two distinct kinds of it, Highland dancing and Scottish country dancing. Highland dancing consists of dances like the sword dance, or Gillie Callum; the fling; and the seann triubhas (which means "old trousers"). It is solo dancing, and though many girls now take part, it should really be danced only by men. Highland dances are danced mainly, though not quite entirely, on the ball of the foot.

Scottish country dancing includes set dances, such as reels and the similar, but generally slower, strathspeys, and also jigs and progressive dances, during which each dancer meets practically every other dancer. Highland dancing is normally accompanied by a single piper, but the accompaniment for Scottish country dancing should be built round Scotland's national musical instrument, the violin. Scotland is also the home of the unusual "mouth music." This is, of course, vocal, but it is not song, being, in fact, an entirely practicable substitute that can be used when no musical instruments are available to accompany dancing.

Ireland also has its reels and its jigs, also normally performed to an accompaniment led by a violin. With lesser-known tunes, people who are not Celtic sometimes find it almost impossible to tell the difference between Scottish and Irish country dance music.

A country that does not spring very readily to mind when one thinks of folk dancing is the United States, but it has its country square-dancing, and, here again, the violin is the prominent accompanying instrument. Many of the tunes used are clearly based on old Scottish and Irish airs that were taken across the Atlantic by emigrants many years ago.

Football. *See* **American Football; Association Football; Australian Football; Canadian Football; Gaelic Football; Public-School Football; Rugby Football.**

Gaelic Football.

Gaelic Football is seldom played by anyone who is not Irish, but it is frequently played outside Ireland, for Irishmen have taken it with them to Britain, the United States, Australia, and South Africa.

Played fifteen-aside, it is a blend of Association and Rugby Football (*q.v.*), the goals having the uprights, cross-bar, and net, exactly as in Association, but having the uprights extended above the cross-bar, as in Rugby. If the ball goes under the cross-bar it is a goal, and if it goes over it is a point, a goal equalling three points. The ball is round, and it may be kicked or caught, but not thrown forward, nor carried, though it may be dribbled by bouncing it. In its essentials, it is probably simpler than most other forms of football, but it is fast and involves frequent hard bodily contact. Substitutes are permitted in case of injury.

Gaelic Football joins with Hurling (*q.v*) in coming under the old-established Gaelic Athletic Association.

Gliding.

The first serious efforts to develop Gliding, which is flying in engineless aircraft or sailplanes, took place in Germany in 1919, and were successful enough to lead to experiments in France and England, where it arrived in 1922. At that time, however, it failed to gain much support, and the real history of gliding in Britain dates from a second attempt to encourage it in 1929. Little more than ten years later, gliding had advanced sufficiently to be a real factor in the Second World War.

Normally launched from hills and by catapult, gliders at first achieved nothing more than small hops. These were followed by steady descents from high hills, and, eventually, by the achievement that ensured the success of the idea, ascents to points higher than the starting-point; for, with altitude, flights of considerable duration, and also over considerable distances, became possible. The altitude is gained by using air currents, which, when the wind strikes the hills that are the ideal starting-points, must rise, and must, if the force of the wind is strong enough to overcome the sinking speed of the glider, carry the glider upwards. Skilful use of air currents enables the glider pilot to stay up, and skilful use of the rising currents beneath clouds enables him to cover long distances by hopping from cloud to cloud.

The extent to which gliding has developed can be gathered from the fact that world championships now take place, and that, in Britain in one recent year, gliding enthusiasts made over 180,000 flights of a total duration of nearly 25,000 hours, and covering altogether over 56,000 miles. Gliders can now reach altitudes of over 40,000 feet, stay in the air for over 50 hours, and carry

out flights of hundreds of miles. Both men and women pilot gliders, and the best pilots are often people in their forties and fifties.

Golf.

Golf, a game of great antiquity, originated in Scotland, and is now widely popular in many countries. It consists of using a set of clubs with which to play a small white ball over a cross-country course of eighteen holes. Each hole will be several hundred yards long, and will have its fixed starting-point and its finish with an actual hole in the ground, the object being to complete the course, which will be several miles long, in as few strokes as possible.

The playing of each hole falls into three sections, driving, approaching, and putting. The starting-point will be a flat piece of ground on which the player will "tee up" his ball on a small rubber peg, or "tee," which he will carry round with him. He will then hit the ball towards the hole, concentrating on achieving distance. From the tee to near the hole is the "fairway," which will consist of fairly smooth ground, not entirely devoid of natural obstacles, and probably containing some sand traps, or "bunkers." On each side of the fairway is the "rough," which may consist of long grass, shrubs, woods, or even roads. The player will continue to play his ball towards the hole, concentrating now chiefly on direction. On the fairway or off it, he should always play his ball where it lies, but, should it be quite unplayable, or even lost, he may drop it or a new one, and pay a stroke penalty for the privilege. The actual hole will be on the "green," a rough circle of exceptionally well tended grass, and, once on it, the player will cover the last few yards by the more delicate art of "putting."

There are many different types of club, players being limited to fourteen. The shafts are generally steel, the striking surfaces being iron or, in the case of drivers, wood. The different "irons" have numbers, but golf clubs used to have special names, often descriptive of their functions, for instance, lofter, cleek, mashie, niblick, and even blaster. Originally, most golf courses were by the sea, and these were called "links," a term now loosely applied to any course.

There are two actual methods of competitive play, match play and medal play. Match play is by holes, a player completing any hole in fewer strokes than his opponent winning that hole. Once a player leads by more holes than there are still to play, the game finishes, the victory being by *X* and *Y*, where *X* is the number of holes he is "up," and *Y* the lesser number of unplayed holes. When a player leads by the same number of holes as there are still to play he is said to be "dormy" so many. Opponents level after eighteen holes proceed to the first hole, and play on until one is one hole up, when he is said to have won at the 19th, 20th, or whatever it may be. Some important match-play events are over 36 holes, or two complete rounds. Medal play is simply stroke play, the result depending on the number of strokes needed to complete the course. This demands a higher level of consistency, for one bad spell can ruin the total, whereas, in match play, it may cost only one hole. In play after the initial drive, the player farthest from the hole normally plays before his opponent.

In match-play championships and tournaments players are drawn against each other, the winners going on to the next round, and so on up to the final. In medal-play events players go round in pairs, but each is, of course, playing against the whole field. Team matches consist of singles and foursomes, in which the partners play shots in turn. Other, less-formal forms of golf are four-ball foursomes, in which each player plays his own ball; best-ball foursomes, in which both partners drive, but, thereafter, play in turn only at the most successfully driven ball; and threesomes, in which each player plays for himself against the others. During a match, a player must not receive advice from anyone except his "caddie," if he has one, the caddie being an attendant who makes a profession of carrying golfers' clubs round.

Every course has its "bogey" and "par" figures, these being scores, with par representing the higher standard that a first-class player might achieve for the course. By assessing a member's own scores against these figures, clubs can allocate a handicap which indicates the player's standard. There are many minor competitions in which golfers play, not on level terms, but from their handicaps, which also serve as a perpetual incentive to players to improve their game, and therefore their handicaps. The possession of a handicap also makes it easier for players to arrange even matches with strangers. Handicaps are subject to alteration as a player's standard changes, and such alterations may be in either direction. The operation of the handicap in play takes the form of strokes deducted from the actual score at certain holes, in accordance with the arrangements in force at any particular club.

Golf offers a tremendous number of competitions of all standards, as well as championships and team matches. Probably the four most important individual championships are the British Open, the British Amateur, the American Open, and the American Amateur. These are long-established, but the two major international team events are quite new. They are the Canada Cup, open to teams of two professionals from any country, and the Eisenhower Cup, for teams of four amateurs, the three best scores counting, from any country. Other, much older international team events include the Ryder, Walker, and Curtis Cups, which are contests between Britain and the United States for professionals, amateurs, and women, respectively; though it is interesting to note that the actual inscription on the Curtis Cup indicates that this trophy is open to women golfers of any country.

Golf is ruled by the Royal and Ancient Club of St. Andrews, Scotland, which is recognised all over the world as the game's headquarters. There was an unusual illustration of this widespread recognition when the Eisenhower Cup competition was instituted by the United States in 1958, for, at the special request of the American organisers, the first meeting took place, not in the United States, but at St. Andrews. The Royal and Ancient Club makes the rules of golf, but these are generally supplemented by local rules in force at particular clubs.

The popular expression "rub of the green," used to describe an unexpected and unavoidable mischance, comes from golf, where it is used when a putt fails to take the expected line because of a slight flaw in the normally perfect turf of the green.

Gymnastics.

Gymnastics is a system of exercising with apparatus, and also a competitive sport, the chief items of apparatus used being the horizontal bar, the parallel bars, rings, ropes, ladders, and the vaulting horse. The horizontal bar, the parallel bars, and the rings can all be used for similar exercises, some being fast swings and others slow movements requiring considerable strength. Strength and swinging also come into ladder exercises; and the rope, which can be climbed in several different ways, is a simple form of apparatus that demands, and will develop, strength. The horse can be used for a variety of vaults, in either the lengthways or sideways position, and still others are possible when pommels are fitted to it. In addition to those who specialise in gymnastics, many sportsmen of various kinds regularly attend gymnastic classes as part of their training for their own particular activities.

Hockey.

Hockey originated about three-quarters of a century ago as a game confined to Britain, but with rules that varied in each of the home countries. However, in 1900, England, Ireland, and Wales combined to form the International Hockey Board, with a view to formulating rules that would apply wherever the game was played, and, two years later, Scotland joined the alliance. The game was also taken up with terrific enthusiasm in India, and Indian players became, and remain, the best players in the world. Their enthusiasm extended to what is now Pakistan, so the division that brought that country into existence also added one more to the list of hockey-playing countries, and without noticeably weakening India's own national team.

Hockey is now played in many other countries, but, for some time, it made little progress on the Continent. Eventually, though, it was tried, liked, and adopted in a number of European countries, and one of these, the Netherlands, has now established a right to a place alongside India, Pakistan, and Britain as the game's top layer. Hockey has, and has long had, Olympic Games status.

Hockey is played eleven-aside on a pitch marked out as in the accompanying diagram, the normal positions of the players being a goalkeeper, two full-backs, three half-backs, and five forwards, exactly as in Association Football (*q.v.*). The white ball can be either sewn, as is a cricket ball, or seamless, and it must weigh from $5\frac{1}{2}$ to $5\frac{3}{4}$ ounces. Sticks must weigh from 12 to 28 ounces, and have a handle that can be passed through a ring with an inside diameter of 2 inches. They have a striking surface on the left side only, left-handed sticks not being permitted. A game consists of two 35-minute halves, unless the captains have agreed on a shorter period.

The game is started, and restarted after half-time and after a goal, by a bully at the centre of the ground. The players bullying stand facing the side-line, each with his own goal on his right. Each taps the ground between the ball and his own goal and his opponent's stick over the ball three times alternately, after which one of them must play the ball. At any bully, all the other players must be 5 yards from the ball, and between it and their own goal.

In play, the ball must be propelled only by the stick, and it must not be stopped with any part of the body except the hand, in which case it must only be stopped, and not caught or knocked forward. These prohibitions, however, do not apply to goalkeepers, who may stop the ball with any part of their body, and also kick it, when in their circle. No part of a player's stick must be raised above the shoulder either at the beginning or end of a stroke, or to stop the ball. Hitting the ball in the air and scooping it are allowed, but deliberate undercutting is not, and umpires can penalise any hit which they judge to be dangerous. Interfering with an opponent's stick, running between an opponent and the ball; and charging or other bodily contact are not allowed. Players must not tackle from the left unless they can play the ball without touching the opponent or his stick.

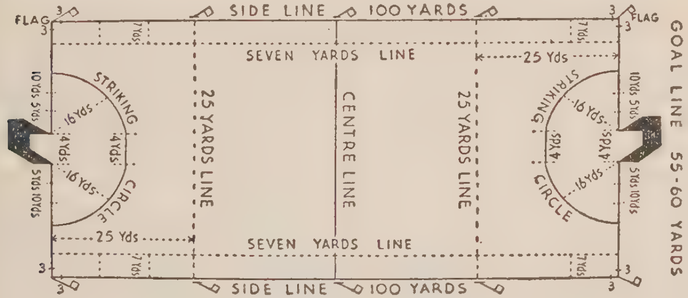
A player is "offside" if there are fewer than three opponents between him and the goal-line, unless he is in his own half, or unless a team-mate playing the ball is nearer to the goal-line than he is. A player who is offside is put onside if an opponent plays the ball, but not if the ball merely touches or glances off the opponent. Players who are offside are not penalised if they do not interfere with the play.

If the ball crosses the side-line it is rolled in by a player of the side that did not put it out. This player must have his hands, feet, and stick outside the field of play, and he must not play the ball again until someone else has done so. All the other players must have their feet and sticks inside the 7-yard line until the ball leaves the roller's hand.

If the ball is sent across the goal-line wide of the goal by an attacker, or, unintentionally, by a defender who is more than 25 yards from the goal-line, the restart is by a bully on the 25-yard line. If it is hit behind unintentionally by a defender who is within 25 yards of the goal-line, a corner is awarded to the attacking side. If it is hit behind intentionally by a defender from any part of the ground, a short, or penalty, corner is awarded to the attacking side. A corner is a hit from a point on either the goal-line or the side-line within 3 yards of the corner flag, while a short corner is a hit from a point on the goal-line 10 yards from the nearer goal-post. At a corner, all the defenders must be behind the goal-line, and all the attackers outside the circle. When the corner hit comes into the circle, attackers are not allowed to take a first-time shot, but must first stop the ball or slow it down. At no time during the game can a goal be scored unless it was hit from inside the circle.

Penalties for infringements outside the circles are generally free hits. Penalties for infringements inside the circle by defenders are short corners, unless they have been deliberately committed to prevent a goal, or have, in fact, prevented a goal, in which cases a penalty bully is awarded. In extreme cases, both short corners and penalty bullies can be awarded for offences anywhere behind the 25-yard line.

A penalty bully is a duel between the offender and one opponent, taking place in the circle, and with all the other players, including the goalkeeper, if he is not the offender, beyond the 25-yard line. The players bully 5 yards from the centre of the goal, and play between them continues until either the attacker scores or hits the



GROUND.—100 yards by 55 to 60 yards. OPENING OF GOAL.—7 feet by 12 feet.
Diagram of Ground as marked out for Hockey.

ball behind or hits the ball out of the circle, or the defender hits it out of the circle. If the defender hits it behind, the bully is restarted. If no goal results, the game is restarted by a bully on the 25-yard line.

A game is controlled by two umpires, each of whom takes one half of the field and one complete side-line. Substitutes are not permitted in hockey.

Hockey is entirely an amateur game. Almost every match is a friendly, for, in Britain, there are no leagues and only a very few rather specialised cup competitions. There are, however, a great many representative games, from county matches up to internationals.

A major feature of the hockey season, which normally lasts from October until March, is the end-of-season Easter Hockey Festival. There are actually several festivals, most of them taking place at seaside resorts. Teams go to them from many different areas, including the Continent, and play three or four matches in four days against opponents whom they would not normally meet. Six-aside tournaments also take place occasionally during the season.

Hockey is played by women, as well as men, and there is a certain amount of mixed hockey between teams composed of both men and women.

Hurling.

Hurling, which might loosely be called the Irish brand of Hockey (*q.v.*), is played fifteen-aside, and has been described as the fastest game using a ball in the world. The ball, called the "slitter," and the sticks, called "hurleys," bear some resemblance to Hockey's ball and sticks, but nothing like Hockey's "sticks" rule applies. The slitter may be hit at any height, and with either side of the hurley, and it may be kicked or caught, though it must not be carried more than three steps, nor picked up off the ground. There is no offside, apart from the fact that attackers must not enter the parallelogram marked out near the goal ahead of the slitter. The goals have uprights that are extended above the cross-bar, and scoring is by goals, under the bar, and points, over the bar, a goal equalling three points. There is a good deal of bodily contact and substitutes are permitted for injured players.

Hurling, rarely played by anyone who is not Irish, but often played by Irishmen outside Ireland, is of great antiquity, and the English authorities in Ireland first tried to suppress it six hundred years ago. It was kept alive, however, and it is very much alive to-day. To Irishmen, Hurling and Gaelic Football (*q.v.*) are symbols of nationalism and patriotism. They are governed by the Gaelic Athletic Association, which has a rule that states: "Any member who plays or encourages Rugby, Association Football, Hockey or Cricket by that very fact incurs immediate suspension from membership of the Association."

A form of Hurling with slightly different rules, called Shinty, is still preserved in another Celtic country, Scotland.

Ice Skating. *See* **Skating.**

Judo. *See* **Wrestling.**

Knur and Spell. *See* **Old English Games and Customs.**

Korfball.

Korfball is a team game with several unique features, the most striking being that it is a mixed game, a team consisting of twelve players, six being men and six women. The game resembles Basketball (*q.v.*) in some ways, the goals, which are 11½ feet high, and the scoring of goals being similar. It can be played on any firm surface, the pitch measuring 300 feet by 133 feet, though a smaller pitch can be used, provided that length and width are reduced in proportion. The pitch is divided into three sections, and players do not move from one sector to another during actual play. They must, however, change to another zone after every two goals. This encourages all-round attacking and defensive ability, and ensures that, even in a one-sided match, every player gets a fair share of the game. Four players from each team play in each section, and players always mark opponents of their own sex. Players must not run with the ball which is advanced purely by passing. There is no tackling, and the ball can only pass from one team to the other by interception. Players may not score if there is an opponent within arm's length. A game lasts for 90 minutes, divided into two halves.

Korfball originated in the Netherlands, where it was first played in 1902. It spread to Belgium in 1927, and reached England in 1947. There is a British Korfball Association, and also an International Board, on which the Netherlands, Belgium, and England are represented. International inter-club matches are a regular feature of the game. Though really a winter game, Korfball is actually played all the year round, the international games between clubs from the three Korfball countries taking place during the summer.

Lacrosse.

Lacrosse, which originated from a game played by the Red Indians, was introduced into England from Canada in 1867, and has been played here ever since.

Basically, it is, perhaps, the simplest of all field team games. The object is the propelling of a rubber ball through goals 6 feet wide and 6 feet high with a wooden "crosse" not more than a foot wide at its widest point, where there is a "mesh" of strings. The goals are from 90 to 110 yards apart, but play can take place behind them, for there are no boundaries to the pitch except the natural borders of the field, unless the captains have agreed otherwise. The only lines required are the centre circle, the goal-lines, and the goal-creases.

In England teams consist of twelve players, but in Canada and the United States the number was reduced to ten some years ago. Players line up right down the field, instead of only in their own half, and there is no offside, except that no attacker may enter the goal-crease before the ball. Should a player leave the field through injury, his opponents must also withdraw a man.

A game consists of four 20-minute periods, but the captains can agree to vary this, either to two 45-minute halves or otherwise. The game is started or re-started after a stoppage by one player from each side "facing" by placing the ball on the ground between the backs of the two crosses, and then drawing them apart, after which the ball is in play. It can then be advanced by running with it on the crosse, throwing it from the crosse, or kicking it, though no goal, except an "own goal," can be scored by a kick. Only the goalkeeper, who can deflect the ball with his hand, but not catch or throw it, may handle the ball. Players can shoulder opponents when trying to get the ball off the ground, and "body check" them by simply standing in front of them to impede them. A player can also check an opponent's crosse with his own crosse if the opponent has the ball. A foul is penalised by giving the non-offending player a "free position," which means that he is given the ball, and the game is then re-started.

Lacrosse demands speed and stamina, and a high level of skill demands practice, but it is not hard for a beginner to grasp the main objects or master the comparatively simple rules.

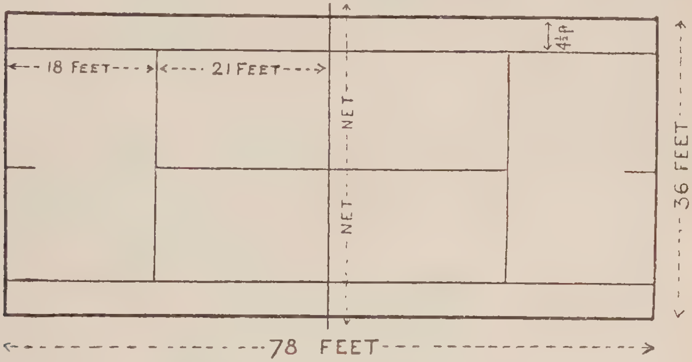
It is interesting to note that Lacrosse, which can be one of the roughest of all games, has been made a suitable game for women by very simple measures, such as the elimination of the body

check; and that there are now more women playing than there are men.

Lawn Tennis.

Originally called Sphairistike—or "Sticky" by those who disliked it—Lawn Tennis was invented in the seventies of the last century as a simplified, outdoor version of Real Tennis (q.v.), using a net, but no walls. It is now far more widely played than the parent game, being popular almost all over the world. As its name implies, it was originally intended to be played on grass, but it is now also played on hard courts of various surfaces, and indoors on wood.

The court is as shown in the accompanying diagram, the outer long boundary lines being the limitations for doubles, and those parallel to them being the boundaries for singles. Both server and receiver score, four points making a game, six games won a set, and two out of three or three out of five sets won a match. Game points are scored "15," "30," "40," and "Game." The system of "vantage" games and sets is used. This means that, if 40-all—called "deuce"—is reached, a player must gain a clear lead of two points to win the game, the winner of the first point after deuce being said to have the "advantage." If the games reach 5-all, the set continues until one player has a clear lead of two games.



NET:—Height 3 ft. 6 in. at posts, 3 ft. at centre.
Diagram of Ground as marked out for Lawn Tennis.

When the game began, there was considerable discussion before this scoring, which is taken from Tennis, was given preference over the straightforward one-two-three system of Rackets (*q.v.*). Much more recently, experiments have been made with the equally straightforward system of Table Tennis (*q.v.*), but the Tennis system survived these, and remains in force.

Service is almost invariably overhand, and the receiver plays the service after one bounce. Thereafter, strokes may be "ground" strokes, played after one bounce, or volleys, played before any bounce. In doubles, either partner may play the ball, but each must serve in turn.

In addition to being played by thousands of people, Lawn Tennis attracts large crowds of spectators. The big annual tournaments, such as Wimbledon, Forest Hills, and Paris, are amongst the major sporting events of the year; as are the Davis Cup competition, open to teams of men from every country in the world, and the Wightman Cup, a women's contest between Britain and the United States. All these events are amateur; but the game also has a top layer of professionals, whose annual world tours are a great attraction.

Marbles.

See Old English Games and Customs.

Modern Pentathlon.

Imagine a king's messenger riding with an important dispatch, and being hotly pursued. His horse is shot, and he has to engage his pursuers, first with his revolver, and then with the sword. Eventually, he breaks away, swims a river, and finishes his journey on foot and running.

That is the "plot" on which is based one of the most interesting, exciting, and testing of all sporting events, the Modern Pentathlon. Often wrongly thought to be a part of Athletics, the Pentathlon is a separate sport, but one that actually consists of five different sports: the five activities, in fact, of the king's messenger in the story, riding, revolver shooting, fencing, swimming, and running. True, the Pentathlon competitor does not have to carry them out one after the other, but he does have to take part in them in that order, one on each of five successive days, both riding and running being across country, the riding on a horse strange to him.

The Pentathlon first appeared in the Olympic Games of 1912, but, in recent years, it has become so popular that, in addition to the Olympic event every four years, there are now annual world championships, as well as national championships in many countries, including Britain. The event was originally designed as one suitable for Army officers, and, though present-day Army training is rather different, most Pentathlon competitors are still servicemen, though they are not all officers. However, a civilian has won the Olympic event, and, in Britain, the Army authorities are willing to provide training facilities for civilian competitors who show signs of reaching a high standard. Many people believe that the "keys" to success in the Modern Pentathlon are swimming and running, and that competitors who are good at them can be taught the riding, shooting, and fencing without too much difficulty.

Mountaineering.

It is difficult to say when Mountaineering, which is the climbing of mountains, not for any scientific reason, but purely for the sense of achievement and for sport, began, but, by the middle of the sixteenth century, Zürich student had formed an Alpine club, and the value and uses of ropes and even dark glasses were known. Amongst famous peaks, Mont Blanc was first conquered in 1786, the Jungfrau in 1811, and the Wetterhorn in 1854. By then, Mountaineering

was becoming organised, and there were systematic assaults on the Alps; in Norway, the Caucasus, and Corsica; in the Rockies and the Andes; in Japan, New Zealand, and Kenya; and, of course, in the Himalayas, where over thirty years passed between the first assault on Everest and its conquest. There are still unconquered peaks in the Himalayas, but it is not only first ascents that interest mountaineers, who can find exciting sport in many parts of the world.

The way to master Mountaineering is to accompany and watch experts. The essential qualities include perfect physical fitness and perfect nervous fitness, and to them must eventually be added a detailed knowledge of snow, ice, avalanches, glaciers, crevasses, and cornices, as well as of the different techniques of ascending, descending, and traversing. Also to be learned is step-cutting, which is hard manual labour carried out under difficult conditions that are also conditions that make perfect workmanship literally a matter of life and death. Clothing, including properly nailed boots, and equipment, including ropes, ice axes, knives, maps, compasses, medical supplies, and a number of other things, must be of the best, and yet, at the same time, it must be light.

Apart from the more obvious dangers, one of the ills to which the mountaineer is heir is mountain sickness, which may take one or more of several forms, including actual sickness, headaches, drowsiness, shortness of breath and palpitations, and general bodily weakness, particularly in the legs. These are about the last sensations that a man engaged in an ascent would choose to experience, but, at high altitudes, the only way to avoid them is by using oxygen.

Rock-climbing. Mountaineering is generally taken to mean snow and ice climbing, but allied to it is Rock-climbing, which demands the same perfect physical and nervous condition, and, in place of knowledge of snow and ice, knowledge of several very different kinds of rock. Ascending, descending, and traversing all apply, and so do ropes, and the rock-climber should, in fact, be something of a knot expert. Light, rope-soled shoes replace the mountaineer's nailed boots. Skye is a favourite haunt of rock-climbers, and, in view of what might justifiably be called the antiquity of climbing, it is surprising to note that the highest peak in Skye, Sgurr Alasdair, was not conquered until 1873.

Netball.

Netball, which is played exclusively by women, is similar to Basketball (*q.v.*), but it is played seven-aside, does not allow substitutes, and the goals have no backboards. It is almost always played outdoors on asphalt or grass.

Nine Men's Morris. *See* **Old English Games and Customs.**

Old English Games and Customs.

The story of England had its beginnings a very long time ago, and many of England's present-day customs, recreations, sports, and games can be traced far back in that story. Some, of course, have undergone very considerable changes, but the links with the past are still clear.

On 1 May, for instance, girls still awake in some villages to the realisation that they are to be May Queens, and to reign for a day, though they may not realise that they are preserving a custom that can point to origins in the days of the Druids, and that, in Tudor times, would have sent them and their fellow villagers out to spend the preceding night in the woods, gathering branches of trees and flowers with which to decorate their houses. Maypoles and morris dancers also belonged to May Day, and they can still be seen in England, and not only on that day.

More local, even quainter, but equally traditional is the trial for the Dunmow Flitch of Bacon in the village of Dunmow in Essex. The original conditions offer this award to any married couple who will go to the twelfth-century Augustinian priory, and there kneel on two sharp-pointed stones and swear that they have neither quarrelled nor repented of their marriage within a year and a day of its celebration. This award has lasted into modern times, not annually, it is true; but then it never was given annually, for it was instituted in 1244, and first claimed in 1445.

One annual event that is as traditional as it is strenuous in the Whit Monday cheese-chase at the village of Brockworth, near Gloucester. Records of this go back to the days of the Stuarts, for that was when they started to keep records of a custom that was already old then: so old that its origins are unknown, though they had to do with the villagers' cattle-grazing rights. A massive round cheese is rolled down nearby Coopers Hill, which has a gradient of one in four throughout its 150 yards; and, with a certain amount of risk to life and limb, the chasers tear down after it, the cheese being the prize for whoever catches it. Sometimes, the cheese hits a bump, and literally leaps out of reach over the hedge at the bottom of the hill, but the chase continues, the prize going to the first pursuer to reach the hedge, where "catchers" wait to halt the headlong rush of the runners. Despite the obvious dangers, the records to date mention nothing worse than a sprained ankle.

This brings us into the realm of sports and games; and, though the most popular game of to-day, Football, is, in anything like the form in which we now know it, a comparatively recent growth, it can claim some relationship with the customs of an earlier day. For its remote ancestry, it might point to Harpastum and Campball, which existed before the Norman Conquest; and it can certainly claim to have been one of a batch of popular recreations banned in the interests of Archery. The football of those and later days, however, took the form of struggles between whole villages, the players battling *en masse* over a cross-country course of several miles. People past whose houses the battle was likely to rage prudently barred and shuttered all windows and doors, awaited the cessation of hostilities with anxiety, and probably helped to push this particular custom into oblivion.

The oldest English games are old indeed, and not only Football, but Cricket, too, had its remote ancestors, from which the descent to to-day can be traced rather more directly. They included Creag, Cat and Dog, and Rounders. Creag, which was played at the time of Edward II, used a curved stick, called a "cryc," as a bat, and a tree-stump as a wicket. Cat and Dog, which came later, was a game for three, two batsmen defending holes 13 yards apart, and trying to hit away the piece of wood that the third player aimed at the holes, the bats being the "dogs" and the piece of wood the "cat." It is interesting to note that Baseball's accepted ancestors are games called One Old Cat and Two Old Cat, which is a clear indication of a common origin for cricket and baseball. Though these and other games have places in Cricket's ancestry, some of them remained popular after Cricket had arrived, and rounders is still a popular children's game.

The beginning of Athletics can also be found in old England. Putting the weight and casting the bar, which was a forerunner of throwing the hammer, were popular with the courtiers in Tudor days, while other events, including javelin throwing, were practised by ordinary people of the same period. Later on, the early hammer throwing also spread beyond the Court, and was even attempted by women, which modern hammer throwing is not.

Tournaments and jousts were popular from the Middle Ages until Tudor times. These were combats between mounted men, a joust being single combat, while a tournament involved many contestants. They were succeeded by dismounted combats, which still take place to-day in the sport of Fencing. Those taking part in tournaments and jousts were required to swear an oath to the effect that they were com-

peting purely for sport; and those taking part in the Olympic Games and certain other big sports meetings to-day swear an almost identical oath. Somewhat similar to jousting, but not restricted, as jousting was, to the nobility, was Tilting at the Quintain, which was practised both mounted and on foot, and in which a lance was thrust at a wooden target, which, if not struck accurately, swung round and struck the tilter.

Other old games, clearly the ancestors of modern ones, included Handball, which became Fives, but which is still handball in the United States; Battledore and Shuttlecock, still a children's game, but now developed by adults into Badminton; and Shovelboard, an elaborate game, for the nobility, which consisted of sliding weights down a long table marked with lines, and which is certainly a forerunner of Shove-Ha'-penny. Another probable ancestor of Shove-Ha'penny was Squails, in which a coin was placed in the centre of a round table, and players tried to push their "squails," or discs, as close to the coin as possible, distances being measured by an instrument called a "swoggle." Also known as Skayles and Keels, this game appeared in the sixteenth century, lasted into the nineteenth century, and, under the name of Keels, achieved a poetic mention in Sidney's "Arcadia."

Archery. Archery goes back hundreds of years, to the days when the bow was the chief weapon of war, and, because of that, practice shooting and contests were officially encouraged: encouraged, in fact, to the extent that other popular recreations, like Football, Quoits, and Bowls, that might have interfered with it were banned, though the bans were always largely ignored. Eventually, the bow disappeared from the battlefields, but, to this day, it has remained popular as a means of recreation and sport. Through the centuries, archery contests were generally of three kinds: shooting at a mark, or target; shooting purely for distance, though this was more popular abroad, in countries like Turkey, than in Britain; and shooting at "rovers," in which two or three archers would cover a cross-country course, taking it in turns to select a mark at which to shoot. To-day, archery, which retains enough of tradition in its terminology to remind the archer that he is following in a very long line, consists of shooting at a target containing rings coloured, going from the centre outwards, gold, red, blue, black, and white, the values being respectively, nine, seven, five, three, and one.

Knur and Spell. Knur and Spell belongs to Lancashire and Yorkshire, and originated in a children's game called Trap and Ball. The player uses a wooden club, the striking end of which, called the "pommel," is shaped something like a bottle, though it has a flat hitting surface, with which to hit a small ball, which he himself releases from a trap by means of a trigger. The ball, which is the "knur," weighs ½ ounce, measures 1 inch in diameter, and was originally wooden, though, later, porcelain was used. The trap is the "spell," and consists of a small brass cup with a strong spring, which is kept down by the trigger. The fixing of the spell is an elaborate process requiring the use of a spirit level, and, when it is in position, a player is allowed 10 minutes to adjust the tension of the spring. Players generally have their own spells. Each player has five consecutive hits, or "rises," and scores one point for every 20 yards covered.

Marbles. Marbles is supposed to have been played in ancient Egypt, but its popularity, with adults as well as children, in the England of the Middle Ages entitles it to count as an old English game. Marbles are often made of clay, but better ones are glass, and the best are pure marble. These are called "alleys," or "alley taws." There are several games of marbles, but they all involve the aiming of a marble at a target, which may be another marble or an opening, by bowling or "shooting" it along the ground. In shooting, the marble is held between the thumb and forefinger, with the knuckle of the forefinger on the ground, and is then flicked away.

Perhaps the best-known game is Ring Taw, in which players shoot from one circle at marbles placed in another about 6 feet away. Fortifications and Increase Pound use concentric circles, players shooting at marbles in each circle in turn. Three Holes and Handers involve shooting at holes in the ground; Arch Board or Bridge, at arches in an upright board; and Die Shot, at another marble on which a numbered die is balanced.

Nine Men's Morris. Nine Men's Morris is a fourteenth-century game for two, usually played outdoors on a diagram marked on the ground, but sometimes played indoors on a board. The diagram consists of three squares drawn inside each other. In addition to the outlines of each square, there are lines from the centre of each side of the inmost square, through the centre of the sides of the middle square, to the centre of the sides of the outermost square. The corner of each square and the centre of each side are the 24 points of importance in the game. Each player has nine men, often counters, and they play in turn, placing a man at an unoccupied point, and endeavouring to place three men in one row, continuing, when all the men are placed, to try to form rows by moving men along the lines. The completion of a row entitles a player to remove, or "pound," one of his opponent's men, the object of the game being either the capture of all the opposing men or blocking them so that they cannot move. The game has many variations, and many names, including ninepenny morris; fivepenny morris, for a version played with five men; and merils, marls, marrels, morals, morris and miracles, all for a version played with three men.

Pall-Mall. Two London thoroughfares, Pall Mall and the Mall, are reminders that Pall-Mall was once popular. Often described as a forerunner of Croquet, it was really more like a form of Golf, a game that arrived at about the same time, both having a common, if remote, ancestor in the Roman game, Paganica. In Paganica players walked across fields hitting a small, leather ball at trees with a curved stick, the object being to reach the target in the fewest possible strokes. It was played by country people, whereas pall-mall, which achieved rapid popularity in the seventeenth century, was a game for the nobility, though other people played simplified versions of it. Pall-Mall was played in special alleys, sometimes ½ mile long, and often surrounded by walls. A boxwood ball a foot in circumference had to be played down the alley, in which were a number of iron arches, in the fewest possible strokes. The player drove off as in golf, but, on reaching the arches, not only changed his club, but also substituted a small steel ball for the boxwood one.

Quoits. Dating back to the fifteenth century, Quoits is one of those ancient games that had the distinction of being banned because its popularity was such that it was believed to be keeping people from archery practice. The ban was not effective, and it continues to this day, though it is now less played than it used to be, Scotland, the North of England, and Suffolk being, perhaps, the last main strongholds. The pitch consists of two circles or squares of clay, 18 yards apart, and each having in its centre an iron pin, called the "hub," 1 inch of which remains above the surface. The quoits are iron rings with a diameter that must not exceed 8⅝ inches. The weight is not fixed, but is often 3 lb. or more. The object of the game, which can be either "singles" or "doubles," is to throw the quoit over or near the hub from the opposite point, 18 yards away, one point being scored for each quoit nearer the hub than the opponent's quoits, and two being awarded for a quoit that drops over the hub, called a "ringer." No points are awarded if opposing quoits are the same distance from the hub, and none are awarded if each side has a ringer. A game is 11 points in "singles," and 15

points in "doubles." Quoits developed from pitching actual horseshoes, and, to this day, some players make their first practice attempts at it with horseshoes. It is, in fact, to the large-scale disappearance of horses, and, therefore, of horseshoes, from country life that some people attribute the drop in the popularity of quoits. It is interesting to note that, in the United States, horseshoe pitching itself is a game, and one that is still popular.

Shove-Ha'penny. Shove-Ha'penny is an old English game that still retains an enthusiastic following. It uses a board, made of wood or slate, and divided by parallel lines across it into nine spaces, or "beds," the edges of the board being cushioned. The "halfpennies" may be actual halfpennies, but they are more often round metal discs. The object of the game is to shove the halfpennies into one of the nine beds, the shoving usually being done with the ball of the thumb, though any part of the hand may be used. First turn is decided by shoving halfpennies at the number nine bed, the best attempt winning. A turn consists of five halfpennies, and the winner is the first player to shove three halfpennies into each bed, halfpennies that touch the cushion not counting. Should a player place more than three halfpennies in any bed, his opponent can claim the excess ones, if he needs them, but the final point of a game cannot be won in this way.

Skittles. An ancient game, played in a special alley, level, about 12 yards long, and 3 or 4 yards wide, Skittles consists of throwing a flat-sided, wooden ball, weighing about 10 lb. and called a "cheese," at nine pins, each weighing 7–9 lb. arranged in a diamond formation 6–8 yards away, the thrower being allowed one forward step while throwing. Scoring is either by knocking down as many pins as possible in a fixed number of throws, or by knocking down 31 in the fewest possible throws. Still another method is to try to knock down the full set of nine in three or fewer throws. Alternative games include one using four pins, and Dutch Skittles, in which a round ball is bowled, and the centre, or "king," pin must be hit first. This resembles the American game, Bowling, which uses ten pins, the tenth having been added when "Ninepins" was made illegal because of the gambling on it.

Stoolball. Yet another ancestor of Cricket, Stoolball is still a popular girls' game. The wicket is a board a foot square on a pole 4 feet 8 inches high, the bat has a round striking surface, and the ball is rubber. Wickets are 16 yards apart, and ten balls constitute an over.

Parachute Jumping

Parachute jumping is generally regarded as a last-resort safety measure, to be undertaken only in a supreme emergency, and with considerable anxiety; but it is now also a recreation and a competitive sport, practised entirely voluntarily, and for enjoyment. This form of jumping may be said to have grown out of the Second World War, in which jumping was used to a far greater extent than ever before, and not only for escape in an emergency. Now, international competitions take place, and the sport has an enthusiastic following in Britain.

Parachute jumping as a sport involves jumps of particular kinds, including landings in a certain area, marked by a circle, and demonstrating turns and body control in the air, the parachutist regulating his direction by pulling down the lines of the parachute. Jumps of this kind may be made from about 6000 feet.

The first point that occurs to many people when they think about Parachute Jumping is that it is extremely dangerous. However, those who jump as a recreation maintain that this is not so, and that it is about as dangerous as skiing. Injuries are few and slight, and, in three years, none of the hundred-odd members of the British Parachute Club, of Fairoaks, Surrey, suffered anything worse than a sprained ankle. The parachutes used are so reliable that they still work even if they have been badly packed. A parachute consists of twenty-eight sections, called "gores," each divided into four panels, so that, even if a hole should stretch right across one gore, which is rare, the remainder of the parachute remains intact, and will bring the jumper down safely. As an additional precaution, jumpers wear a small reserve parachute on the chest, but this is hardly ever needed.

Training, which generally takes place at weekends, starts with a period of learning how to fall, how to judge wind direction and speed, and how to pack a parachute. The first actual jumps are from 1500 feet. Both men and women take part in Parachute Jumping.

Party Games

Parties can be for any of quite a number of age groups; and, when it comes to Party Games, it is not easy to say at what age a particular game ceases or starts to be fun. However, given a number of games from which to choose, the organiser of a party should be able to select those suitable for the occasion and the guests.

Many years of popularity perhaps confer the right to first mention on a batch of "classic" games suitable for young children, starting with Musical Chairs and a less-well-known variation of it. Musical chairs requires a line of chairs, one facing one way, and the next one the opposite way, and so on. Someone starts playing the piano, and the players, who should number one more than the chairs, move round and round them. When the music stops, they sit down quickly, the odd one out dropping out. The game continues with one chair removed, and carries on until the last two players are contending for the last chair. The variation is Going to Jerusalem, which needs a line of chairs similarly placed, and numbering one less than the players, and also a piano accompaniment. The players start seated, the remaining one walking round and round them, chanting "I'm going to Jerusalem." Every now and again, he knocks on the floor behind a chair, and the player seated there must rise and follow him. He carries on, reversing his direction at will, until all the players are following, after which the game is exactly the same as musical chairs.

Hunt the Slipper has all the players except one seated in a circle, with their knees raised so that the slipper can be passed underneath them. The extra player stands either outside or inside the circle, and tries to spot the slipper, and tap a player when he is in possession of it. For Hunt the Thimble, all the players except one go out of the room while the selected player hides the thimble in such a way that it is visible without anything having to be moved. He then summons the others with the formula, "Hot beans and melted butter, ladies and gentlemen, come to supper." The others then search for the thimble, being told if they are "hot," "warm," or "cold." As each player spots it, he sits down quietly, and lets the others continue their search. Up Jenkins has two teams seated on opposite sides of a table, one team having a small coin, which one player holds. The leader of the other side then says, "Up Jenkins," at which the first team hold their hands, with fists clenched, above the table. Next comes a command, which is either "Smash," at which the hands come down flat on the table, or "Crawl," at which they come down clenched and then slowly spread the fingers, the coin holder always complying, but trying to conceal that he has it. The other side then order various hands to be removed, the object being to remove all but the one with the coin.

In Charades a group of players go out of the room and select a word for the others to guess. This should have two syllables, each itself a word. The group then act three short scenes, the first representing the first half of the word, the second the other half, and the third the whole word. There are several ways of acting Charades. In one, each scene actually represents the word or syllable in some way; in another, it has nothing to do with it, but the word or syllable is mentioned; and in still another, it is both represented and mentioned. In historical Charades a well-known figure of fact or fiction with a name containing about five letters is selected, and short scenes are acted about different characters whose names begin with the various letters in the chosen name. Similar to Charades is Dumb Crambo, in which those in the room select two rhyming words, decide on one to be acted, then call in the "actors" and tell them the other. If they start to act a wrong word, the spectators hiss, but, when the right word is reached, they clap. Both actors and audience remain silent. The similarly named Crambo requires each player to write a noun and a question on separate pieces of paper, put them into two hats, draw another paper out of each, and write an answer to the question on one bringing in the noun on the other. Capping Verses is a rhyming game in which one player invents a line, and the others have to supply a rhyming line in the same metre.

Perhaps the most famous of all paper games is Consequences. Each player has a sheet of paper divided into columns, writes an adjective applicable to a man in the first column, folds it over, and passes it on. He then writes a man's name in the second column of the paper he receives, folds and passes it, and carries on with an adjective applicable to a woman, a woman's name, a place, a remark by a man, a remark by a woman, what the consequence was, and what the world said; after which, the papers are read out. Lost and Found is a variation, in which the items required are the object lost, by whom, when, where, by whom it was found, in what condition, where, and what the reward was. A simple paper game is Squares, in which several lines of dots are marked on a sheet of paper. Each player in turn joins two dots with a line, the object being to collect squares, which go to the player who makes the line that completes them. Advertisements has sections of well-known advertisements displayed with the name of the product omitted, players having to write down as many of the names as they can. This is an observation test, as is Kim's Game, in which a number of small objects on a table or a tray are displayed for one minute, after which the players write down as many of them as they can.

Verbal guessing games are numerous. In Proverbs, one player goes out of the room while the others choose a proverb, and allocate one word of it to each person. The player then returns and asks questions, the answers to which must include the speaker's particular word. In Guess Who, a character of fact or fiction is chosen, and has to be guessed by questions that must be answered "Yes" or "No." In How, When, and Where, a noun with several different meanings has to be guessed by questions that are restricted to "How do you like it?" "When do you like it?" and "Where do you like it?" Biographies is a game generally popular with children. An adult tells a brief, but accurate, life story of some famous historical character, omitting any mention of the character's surname. The winner is the first listener to interrupt the story by calling out the missing name.

Perhaps the most popular of all question-and-answer games is Murder, which starts with cards being dealt round so that only the recipients can see them. This is to allot the "parts," one particular card indicating the murderer, and another the detective. The detective announces himself at once, but the murderer keeps quiet. All the lights are then turned out, and the players disperse about the house. The murderer counts fifty, and then commits his murder by pretending to stab another player, who must stand still and count fifteen before screaming to announce the murder. The scream brings the detective, who puts the lights on, and makes what mental notes he wishes of the various players' positions, which, with the exception of the murderer's, must remain unaltered from the moment of the scream. The detective then gathers the players together, and questions them, everyone being compelled to answer truthfully, except the murderer, who can lie as much as he likes, unless he is directly accused by the detective, when he must own up. The detective is allowed three direct accusations. A variation gives an additional part to a detective's assistant, who does the gathering in of the suspects, and reports on their respective positions to the detective.

Finally two word games that generally amuse children. In What's the Word two players quietly select a word with several meanings, and start to discuss one of its meanings, without mentioning the word, soon switching to another meaning, and then another, or else back to the first. If another player thinks he has guessed the word, he joins in the conversation. He is soon proved wrong or right; and, if wrong, he drops out again, but, if right, he then takes over with a partner whom he chooses. Travels gives one player a special part, another acting as an intermediary between him and the others. The player whispers to the intermediary the name of a place, which may be anywhere in the world, to which he intends to travel. The intermediary then asks three others, who do not know the place, one question each, these being "How is he to go there?" "How is he to travel about when he gets there?" and "How is he to come home again?" The answers must be methods of transport, and the first player then tells a brief story of his journeys and adventures, during which he must abide by the means of travel suggested.

Patience.

Patience is a card game for one person, and, though there are few different games for one, there are countless different forms of Patience. There are some using one pack, and others using two, almost all of them starting with the setting out of the cards on the table according to fixed rules, and having as their object the building up of the four suits on their aces.

The game that might almost be called the basic form of single-pack patience starts with a row of seven cards, only the left-hand one being exposed. Underneath this, and overlapping it, comes a row of six cards with the left-hand one exposed, and so on down to a "row" consisting of only a single exposed card, the exposed cards being left uncovered in each decreasing row. The object is to take out first the aces, and then the cards from two up to king, building each suit on its ace. From the "lay out," exposed cards can be moved when it is possible to put one on a card one pip higher in value of the opposite colour, when any card left uncovered by an exposed card can itself be exposed. The undealt cards can be played three at a time, the top one of each three being "playable," with the one underneath becoming "playable," if the top one is, in fact, played. The undealt cards can be played through three at a time in this manner as often as desired. A slight variation of this game allows the undealt cards to be played through one at a time, but this can be done only once.

Another single-pack game starts with a row of nine exposed cards, with, below it and overlapping, a row of eight, and so on down to one, all the cards being exposed, and the right-hand one being left uncovered in each decreasing row. The remaining seven cards form a separate row at the bottom. The object and the "move" are the same as in the previous game, only one card being moved at a time, and any card being eligible to fill any vacancy that might occur in the top row. Cards in the separate row can be played as required, but, once in the "lay out," they must remain there. This game is called King of the Belgians, and the last seven cards are referred to as the Belgian Reserve.

One to Six is a two-pack game. The player deals out a row of four cards, then discards two to a rubbish heap, and carries on like this until all the

cards have been used. If, however, while doing it, he comes across any aces or kings, he takes them out, up to one of each from each suit, subsequently also taking out any that will fit on to these, building up from the aces and down from the kings. Then he goes through the rubbish heap, extracting any cards that will fit on the eight piles. The dealt-out cards, with the rubbish-heap cards, are then dealt again in the same way, the object being to complete the eight built-up suits in three rounds of dealing.

At first sight, it might appear that there is little point in Patience, which does nothing to inculcate "card sense" that might prove useful in ordinary card games. However, the fact that it has its own fascination is shown by the countless thousands who play it at one time or another, and by the virtual inability of anyone seeing a game of Patience in progress to refrain from studying the "lay out," and offering advice. There is scope for a certain amount of skill in the management of the cards, as, for instance, in the first two games described above, in which it is advisable to build up the suit-piles fairly evenly, as a long run in one suit will leave a disproportionate number of cards of one colour, thus restricting further moves.

Polo.

Polo, one of the oldest of all games, originated in Persia, then spread in one form or another to China, Japan, and India, eventually being brought from India to England by cavalry officers in the second half of the nineteenth century. Later, it was enthusiastically taken up in the United States and Argentina. Played four-aside, and mounted, on a pitch that should measure 300 yards by 160 yards, its object is to score goals by hitting a 5-ounce ball through goals 24 feet wide with a stick consisting of a long cane fixed at a slight angle into a wooden or bambo striking head. The game is divided into periods, called "chukkas," the number of periods varying slightly, as may be agreed for particular games.

Formerly, Polo was a game for the wealthy, for it entailed owning and maintaining a string of trained ponies. In recent years, however, certain stables and riding schools have provided facilities for playing and practising Polo, and these facilities include the hiring out of ponies. This apparently simple and obvious step is actually quite a revolutionary innovation that has brought Polo within the reach of almost anyone who wants to play, and thereby increased the popularity of an ancient and exciting game that might otherwise have died out because of the expense involved.

Pot-holing.

Pot-holing might almost be described as mountaineering in reverse, for it consists of the descent, perhaps to a depth of 80 or 90 feet or more, and probably by a precarious rope-ladder, of pot-holes caused by the action of carbon-charged water on rocks of the chalk or limestone type. Pot-holing is pursued as a recreation, but it can also lead to extremely useful geographical and geological discoveries, and it certainly does not lack danger.

Pot-holes are plentiful in Britain, particularly in Derbyshire and Yorkshire, for there are many instances of streams plunging into the earth, to reappear many miles away. While underground, they may alter course considerably, even to the extent of turning almost back on themselves, and they may cross other underground streams. Where many of them reappear, or where many of those that appear start from, is still unknown, for the exploration of these underground courses is of comparatively recent origin, and is still far from complete. It is, in fact, exploration of this type that pot-holers undertake, and, if, in doing it, they subject themselves to considerable discomfort and some danger, they also discover a fascinating, and even beautiful underground world. Once below the ground, even quite small pot-holes often lead to winding passages, tunnels, and underground caverns containing icicle-like formations both descending from the roof and ascending from the ground. Called stalactites and stalagmites, respectively, these sometimes meet to form weird columns and pillars, all these and other strange formations being caused by calcium deposits. Seen in the light of the pot-holers' torches, some of these caverns are wonderful sights, and new tunnels and caverns are always being discovered.

For those who have the nerve for it, Pot-holing can be an enthralling, and also useful, recreation, but it is one that the newcomer should practise only in company with experienced pot-holers, and it is one in which the loss of a torch can be a major disaster.

Public School Football.

All the forms of football popular to-day grew out of the games played at various English Public Schools a century and more ago. These games differed widely, the rules often depending on purely local considerations imposed by the available space. The Rugby game (*q.v.*) in its modern form is, of course, still played, both at that school and far beyond it; and other games that still survive at the schools that originated them are the Eton Field Game, the Eton Wall Game, the Harrow Base Game, and the Winchester Net Game.

Punting.

Punting consists of propelling a long, narrow, flat-bottomed boat with a pole, the punter standing up; and it can be either a pleasant, leisurely recreation or a fairly strenuous competitive sport. The sporting side is governed by the Thames Punting Club, which has headquarters on the Thames at Staines in Middlesex. Women, as well as men, take part in competitive events.

Punting as a sport has the unique distinction of being confined, not only to one country, Britain, but to one river, the Thames; though in some parts of the world boats poled from a standing position are used for various purposes. There have been rumours that Japan has, or had, a similar sport, but these have never been authenticated.

Quoits. *See* Old English Games and Customs.

Race Walking. *See* Athletics, Walking.

Rackets.

Rackets is a fast, racket-and-ball game, played on a court measuring 62 feet by 31 feet, and using walls. A game consists of 15 points, unless 13-all is reached, when the non-server can set the game to 3 or 5, or 14-all is reached, when the non-server can set the game to 3, the game going to the first player to score the prescribed number of points. Only the server scores, the receiver taking over service when he makes a winning shot. When served, the ball must strike the front wall above a line called the "cut" line before striking any other part of the court, but, in play, it may be played either on the volley or after one bounce. If a player impedes his opponent, it is a "let," and the point is re-started.

Real Tennis.

Tennis, sometimes called "Real," "Royal," or "Court" Tennis, is a court game played with rackets and balls that has been called the King of Games, and that was once certainly the game of kings. Henry VIII played, and it is mentioned in Shakespeare's *Henry V*; but the first kings to play were of France, where the game originated.

It is a complicated game, and no description could give anyone who had never seen it an accurate idea of what it is like. Most racket-and-ball games use either a net, over which the

ball is hit, or walls, against which it is hit, but Tennis uses both. Also, in most racket games, players change ends after so many games, but, in Tennis, they may do so during a game. Matches are in games and sets, a player winning six games completing a set towards the two out of three or three out of five that will make the match.

There are not many Tennis players in the country—there are only about a dozen courts—and very few women have ever played. People who do play, however, most of whom play other games as well, are almost unanimous in voting it the best of all games.

It is said that the term "love," used in so many games to indicate "nought," comes from Tennis, the original French term being "l'œuf," which, in that language, actually means "egg": an egg being, of course, something like the figure used for "nought." This derivation is not sufficiently well documented to be accepted as definite fact; but it is interesting to note that, in Cricket (*q.v.*), the term used for a score of "nought" is a "duck," or, in full, a "duck's egg."

Revolver Shooting. *See* **Rifle Shooting.**

Riding and Show-jumping.

The almost complete disappearance of the horse from everyday life has been followed by an increase of interest in Riding as a recreation. This is at least partly due to the great attention paid in recent years by both Press and television to one particular branch of horsemanship, Show-jumping. Before learning to jump, however, it is necessary to learn to ride, and many people never go, and have no wish to go, beyond the ordinary, unspectacular riding for pleasure that is called "hacking."

A great deal has been said and written about "correct" riding style, but, in actual fact, there are many different styles. The cavalryman, for instance, bends the leg to some extent; the Red Indian bends it to a much greater extent, more or less in the style that has been adopted by American jockeys; and the cowboy rides with an absolutely straight leg. Yet all these are expert horsemen. To assist in acquiring the normal English style, which is very close to that of the cavalryman, there is an old jingle that is now much less heard than it used to be, but is probably none the less helpful or accurate for that. It runs: "Your head and your heart keep up. Your hands and your heels keep down. Your knees keep close to your horse's sides, and your elbows close to your own." Old or not, anyone who learns it, and then builds up a certain amount of experience of putting it into actual practice is well on the way to becoming a rider.

It has been said that Riding is excellent exercise for the horse, but, whatever its merits or demerits as a medium of actual physical exercise for the rider, it certainly provides him or her with a delightful and beneficial form of recreation in the open air. For those who like the idea of Riding, no matter how inexperienced they may be, there are "pony trekking" holidays. These take place at fixed centres, where about two days are spent in simple instruction in such elementary things as saddling, mounting, starting, and stopping the horse, after which day expeditions cover the surrounding countryside. Those who feel they would like to combine their Riding with something competitive might start with gymkhanas, which are sports meetings that generally include mounted equivalents of such novelty events as obstacle races and needle-threading races. For the more ambitious, gymkhanas could even be the first step towards the top-class competitive sport of Show-jumping.

Show-jumping. A Show-jumping contest is a mounted competition over a circuit of jumps, which the entrants attempt one at a time, each having the field to himself or herself, and being free to concentrate entirely on the jumps, without having to worry about other riders. The jumps, which have to be taken in a certain order, are of many kinds, including fences, double fences, walls, and water. Scoring is by points against, called "faults," so many being debited against an entrant for falling, knocking down an obstacle or displacing part of it, refusing, and other mistakes. Though the event is in no sense a race, there is normally a time limit that must not be exceeded, and, in some events, bonus points are awarded for fast rounds. Show-jumping is not restricted to riders who own their own horses, for some owners do not want to compete themselves, and are only too pleased to let good horsemen take their jumpers round for them. Incidentally, inexperienced riders taking up jumping for the first time will probably find it advisable to make some slight changes in their method of sitting in the saddle. Jumping needs a firm seat, and the novice rider may find it necessary to shorten the stirrups a little.

Allied to Show-jumping, and coupled with it in the difficult three-day competitions, is dressage. This is simply a mounted display revealing that the horse is obedient, balanced, supple, and, in a word, trained; and is a simplified form of the better-known "haute école," or highly-schooled riding. Good riders who seek absolute perfection can, if they are willing to pay for it, take an intensive course of haute école riding and all forms of horsemanship at the most famous of all riding schools, the Spanish Riding School in Vienna. Courses, which are conducted in German, consist of eight hours training a day for six months, and informality is not encouraged, the regulation dress for students being a bowler hat, black jacket, and white breeches. Riders who fall are immediately assisted by an attendant armed, not with a stretcher, but with a clothes brush.

Rifle Shooting.

Considered as a sport, Rifle Shooting, which might almost be called the modern equivalent of archery, had its origins in virtually the same conditions and circumstances that had popularised the older weapon five hundred years previously; though, unlike archery, it did not enjoy legislation aimed at abolishing other recreations in its favour. Both were encouraged because, in their respective periods, efficiency at them meant, not only success in competitions, but also the most effective defence in time of war, the great period of the rifle's encouragement for this reason being the latter half of the nineteenth century. Archery as a sport survives to the present day, and Rifle Shooting as a sport continues, though it can no longer be regarded as the most effective weapon.

With a normal rifle, with a calibre of about ·300 inch, competitive shooting is at ranges from 200 yards to 1000 yards, and there are many competitions, the greatest of them being the annual contest at Bisley, Surrey, for the Queen's Prize. Almost equally popular, however, is small-bore shooting, with a calibre of ·22 inch, and this, too, offers many annual competitions.

Revolver Shooting. Revolver shooting, often called pistol shooting, is also a competitive sport, and a very difficult one. Impressions gained from cinema and television screens might lead anyone who has never fired one to think that the revolver is an easy weapon to fire without fuss and with devastating effect. It is the very reverse of this. It is fired, not from the hip, but with the extended arm raised, which is how, in real life, it was generally fired in the old West. It is extremely difficult to hit even a man-size target at 10 yards, and very few people can call themselves good revolver shots, just as few of the old Westerners were good revolver shots. The difficulty is caused by the tremendous "kick" of a weapon that is held, not by both hands and pressed into the shoulder, as a rifle is, but by one hand. A revolver has sights, but the normal method of aiming is by using the "instinctive pointing sense," which is based on the fact that, if you point your finger at an object in the ordinary way, without, of course, taking a careful sight along it, you will, in fact, be pointing accurately. The same applies when pointing a revolver.

Rock Climbing. *See* Mountaineering.

Roller Skating. *See* Skating.

Rowing.

Rowing, meaning simply taking a boat out on the sea or a river for a short period, is a pleasant recreation and a healthy exercise, but competitive rowing is one of the most strenuous of all sports.

A racing oarsman either rows, which means that he uses one oar, or sculls, which means two oars. Races are of various kinds, the best-known being for crews of eight oarsmen with a cox. Then there are races for crews of four with cox, and for crews of four without cox. There are also events for pairs with cox, pairs without cox, double sculls, and single sculls. Eights, fours, and pairs row, while double and single scullers, of course, scull. In fours and pairs without cox, and in all sculling, the oarsmen steer themselves.

Race Rowing is mainly a river sport, but there are races on the sea. For these, crews are usually fours with cox, and they use heavier boats than the normal racing "shell." (*See also* **Boat Races.**)

Rugby Fives. *See* Fives.

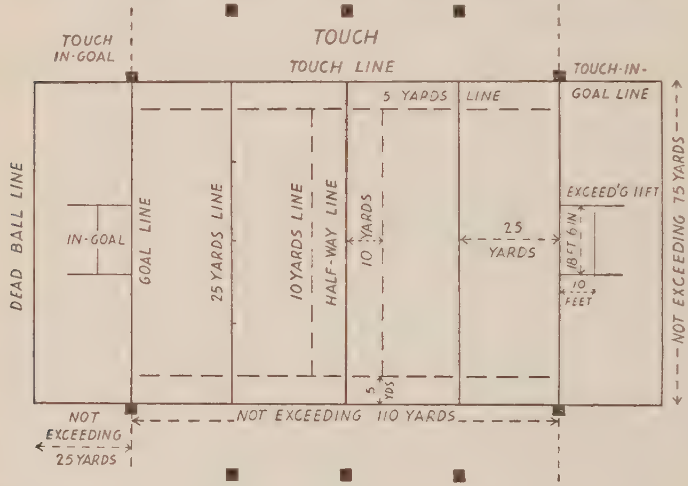
Rugby Football.

As its name implies, Rugby Football is based on the game played at Rugby School in the days when football was not organised and various schools played to their own rules. The story of how the Rugby game originated is well known and widely accepted, but it is definitely not accurate and possibly almost entirely apocryphal.

The story is that, in 1823, a boy named William Webb Ellis disregarded the rules of that time by handling the ball, and that handling was subsequently made legal. In fact, handling the ball by catching it was allowed at Rugby before 1823, so, if Ellis was responsible for an innovation, it was not by handling the ball, but by running with it after catching it. Running with the ball certainly became, and remains, the leading feature of Rugby Football; but the story that Ellis was responsible, though commemorated by a plaque at the school, was first heard years after Ellis's death, and he never knew of the fame that became his. He was definitely at Rugby at the time, though, and, a few years later, he played in the first-ever Oxford and Cambridge cricket match.

The spread of the game beyond the school that originated it has led to, not one, but two games of Rugby Football, Rugby Union and Rugby League. About twenty-five years after the game had become organised, with the Rugby Union as its governing body, there was a dispute on the question of legalising payment for time lost from work by players. The Union would not agree to this, so twenty-two clubs, mainly in Yorkshire, seceded and formed the Northern Union, now the Rugby League. Both bodies originally played the same game, but now, after over sixty years of independent existence, during which each has made various rule changes, there are some important differences.

Rugby was originally played twenty-aside, but it is now fifteen-aside in R.U. and thirteen-aside in R.L., the positions being seven backs and eight forwards in R.U. and seven backs and six forwards in R.L. Played on a pitch marked out as in the diagram, and with an oval ball, Rugby is mainly a handling game, the chief object being the grounding of the ball behind the opponents' goal-line. This is a "try," which counts three points, and entitles the scoring side to an attempt to score a goal by kicking the ball over the crossbar from a point measured in a straight line from where the ball was grounded. Other forms of goal are penalties, which may be awarded anywhere, dropped goals during play, and goals from a "mark," after a player has signalled a "fair catch" of the ball during play by shouting, "Mark." In R.U. goals following tries, called "conversions," count two, and other goals three.



NOTES:—

■ Indicates Post with Flag. Length and breadth of field to be as near to dimensions indicated as possible.

– – – These broken lines indicate 10 yards and 5 yards from half-way and touch lines respectively.

Goal dimensions.—10 feet is taken from the ground to the top edge of the crossbar and 18 feet 6 inches from inside to inside of the goal posts.

In R.L. any goal counts two, but goals from a "mark" are not allowed.

The game is started, and restarted after a score, by a kick-off from the centre; and, thereafter, the ball may be advanced by kicking or carrying. It may also be passed from hand, but not forward. Ball carriers may be tackled and thrown down, and they may "hand off" tacklers with the unclenched hand. A frequent method of restarting after a stoppage is the "scrummage," in which the forwards bend down and push against each other, three from each side constituting a front row, and the remainder two subsequent rows. The ball is then put into the tunnel between the front rows, the centre man of each, the "hooker," endeavouring to gain possession by hooking it back into, and generally right through, his "scrum." In R.L. this method of restarting is used whenever the ball goes out over the touch-line; but in R.U. the ball is thrown in straight along a "line out" of both sets of forwards, unless the side whose throw it is demand a scrummage. In R.L. kicking the ball straight out over the touch-line is allowed only from a free-kick, the penalty being a scrummage at the point from which the ball was kicked. The effect of the differences between the two games is that R.L. is faster and more open, and the ball is more continuously in play. A game lasts for eighty minutes, divided into two halves.

In addition to Britain, both forms of Rugby are played in France, New Zealand, and Australia, and R.U. is played in South Africa. Both codes also have other, smaller "outposts" in various European countries, and there are minor R.U. centres in North and South America. R.U. is entirely an amateur game, and R.L. primarily so, though there is a top layer of clubs using part-time professionals.

Sailing.

Mention of Sailing tends, perhaps, to conjure up visions of large, graceful yachts, beautiful to see, but clearly to be owned only by the wealthy. Sailing to-day, though, is very different from that. It is mainly sailing in small boats, many of them wholly or partly built by their owners. At first glance the building of a boat might seem a tremendous and highly skilled task, but, in actual fact, it can be as big and as hard or as small and as easy as the builder wishes. Some amateur builders start from the very beginning, acquiring the various materials needed bit by bit, and gradually bringing their boats into being. However, those who either lack the time for this or doubt their ability to construct a boat in which they would feel safe on the water can buy complete boat-building kits; and they can buy them at any stage of construction they choose from hardly started to complete except for a coat of paint. It is more economical to build a boat than to buy one complete and ready for launching, and the earlier the stage of construction at which the owner takes over, the greater the saving. Some owners claim that they enjoy the building as much as the sailing, and it is probably true that the owner who has done some work on his boat, however little, takes more interest and pride in the finished article.

The fact that boat-building is now within the reach of practically everyone means, of course, that the end to which it is a means, Sailing, is also within the reach of practically everyone, for few people are far from some suitable stretch of water. Where there is sailing, there are clubs, which the boat owner can join for quite reasonable fees, and which provide either sheltered moorings or "dinghy parks" where the boat can be kept.

Eventually, the small-boat owner may want to try racing his craft, and there are many events for boats of all classes and sizes. Racing is an enthralling pastime, for, though races are, of course, tests of speed, they are also very much more than that. There is tremendous scope for tactics, and the sport is in every sense a highly skilled one, as well, incidentally, as one with an interesting history behind it.

Yacht Racing. The first recorded sailing contest was a race from Greenwich to Gravesend on 1 October 1661, between Charles II, who won, and his brother, the Duke of York. In those days, such contests generally took the form of manœuvring for positions of advantage, rather than straightforward racing, for the Royal Navy also relied on sailing, and every privately owned vessel was a potentially useful naval auxiliary: a fact that emphasises the appropriateness of the right of England's most famous yacht club, the Royal Yacht Squadron, to fly the White Ensign. The club was founded as the Yacht Club in 1815, becoming the Royal Yacht Club in 1817, when the Prince Regent joined, and taking its present name in 1832. In 1851 the club put up for competition a 137-ounce, 100-guinea cup that has become the most famous trophy in yachting, and one of the most famous in sport.

In that year a schooner of the then famous New York pilot-cutter type, called the *America*, sailed across the Atlantic, and her commander challenged the Royal Yacht Squadron to find a schooner or schooners to race against her. There were no takers, so the *America*'s commander made a more tempting offer. Though the schooner rig was considered slow, and was generally given a time allowance in races, he offered to race on level terms against vessels of any rig, and to back his ship for anything up to 10,000 guineas. There were still no takers, so the commander entered for the 53-mile race round the Isle of Wight for the new cup, though he knew that some of the seventeen other yachts in the race were twice the size of the *America*. Despite that, the *America* won by eight minutes.

Subsequently, the *America* was sold to an Englishman, who cut 5 feet off the masts, and then wondered why she did not win races. She was rebuilt in a Thames boatyard, and, when the War Between the States broke out, became a Confederate blockade-runner, but was trapped in the St. John's River, Florida, and scuttled. However, she was raised and repaired, and finished the war as part of the Union Navy, after which she returned to racing, which brings us back to the story of her cup.

The cup, now called the *America*'s Cup, had been given to the New York Yacht Club for perpetual competition between different countries, and the first challenge for it came in 1870. The challenger was defeated, and by the *America*. To date, there have been seventeen challenges, fifteen by Great Britain and two by Canada, but not one of them has succeeded. The 1958 challenge, though, pointed the present trend in yachting, which is towards smaller vessels. Previously, the *America*'s Cup conditions stipulated that races must be between very large yachts, of the "J" or 21-metre type, and that, if the challenge was from across the Atlantic, the challenger must sail across. In 1958 the rule about sailing across the Atlantic was waived, and the event was between yachts of the 12-metre class. Even so, the unsuccessful challenge cost about £100,000.

Large vessels are still seen in the famous Bermuda Race, but the modern trend is very evident in the growing popularity of the annual Folkestone Dinghy Race across the Channel, which also has a class for catamarans, very fast and very popular boats that consist of two boats side by side joined by a kind of raft.

Show-Jumping. *See* **Racing and Show-Jumping.**

Skating.

At first glance, ice-skating would not appear to be a normal activity for British people, for it is a part of Winter Sports (*q.v.*), which are possible in Britain only rarely and to a very small extent, and it was formerly restricted to brief periods

when rivers, lakes, and ponds were frozen. Despite this, however, the people of this country have always appeared to possess a natural talent for it, and they have practised it whenever opportunity offered. The history of British Skating goes back a very long way, and includes occasions when Skating was possible, and took place, on the Thames, as well as many, more regular instances in the Fen district and other places. In recent years this wish to skate on ice has been catered for by the opening of many indoor rinks, which make the skater independent of weather and daylight, and enable Skating to be carried on throughout the year.

Many people ice-skate just for recreation, health, and amusement, but anyone keen to carry Skating a stage farther and acquire a higher level of skill can find a wide range of opportunities from which to choose. Figure-skating is very popular, and for those anxious to test their skill at it there is a series of medal tests, in which the skater is not in competition with anybody, but is attempting only to reach a fixed standard. Beyond these, there are many competitions and championships. Dancing on skates also attracts many people; and also offers those interested standard medal tests and competitions.

Another popular skating activity is speed-skating, which takes place indoors and, whenever possible, outdoors as well, though the methods and techniques of the two forms of racing differ widely. Outdoors, the skaters normally race in pairs, though each man is timed, and is actually racing against the whole field. Much of the racing is on long, straight stretches of ice. Indoors, skaters race perhaps four at a time, and are directly opposed to those on the ice with them. These races are on small tracks, a lap sometimes being no more than 130 yards. Standard outdoor distances range from 500 to 10,000 metres, while indoor races go from 440 yards to 2 miles. There are also indoor relays, generally of 3 miles, in which teams of four race on the "Madison" method, relieving each other, not at fixed points, but at will. In addition to competitions and championships, speed-skaters also have their standard medal tests.

Ice, however, is not the only surface on which Skating takes place, for, following an unusual history, roller-skating also maintains a large following. Roller-skating was originally introduced long before the arrival of the indoor ice rinks purely to provide ice-skaters with some kind of substitute when no natural ice was available. It progressed by fits and starts, varying from extraordinary "crazes" when it seemed that everybody was roller-skating, to periods when nobody appeared to be doing so. Eventually, it settled down to a steady existence as a popular recreation in its own right that has in no sense been pushed into the background by the increased facilities for ice-skating. The opportunities it offers are almost identical with those of ice-skating, for they include figure-skating, dancing, and speed-skating, with championships, competitions, and standard medal tests in all branches.

Both forms of Skating also offer a team game, and in both it is hockey. Ice-hockey, which is called simply hockey in Canada, where it originated, and the United States, is played six-aside, with substitutes permitted, and with a rubber disc, called a "puck," instead of a ball. It first began to win popularity in Britain soon after the First World War, and since then has had rather a chequered career, helped forward by the semi-professional players from Canada, who play in the National League teams, and held back by the lack of facilities for British youngsters to practise; for practice sessions mean closing rinks to all the other forms of Skating for certain periods. The game should, however, survive, for there is a definite demand for it.

Roller-hockey, generally known as rink-hockey, bears a closer resemblance to its parent game, outdoor field hockey, than does ice-hockey. It is played with a ball, and is five-aside, with one substitute permitted. Its popularity is such that it is now played throughout the year.

There is a form of hockey on ice that closely resembles outdoor hockey. This is Bandy, which originated in England, but is no longer played here, though it is popular in Sweden and the U.S.S.R. Some other games have been tried on skates from time to time. One is Badminton, which has been played on ice, but only as a stage exhibition. Basketball on roller-skates has been tried in several countries, and might well develop and spread.

Skating is not so much a recreation, sport, or game as a whole series of different recreations, sports, and games. Each has its following, and, while there are enthusiasts who are interested in both ice- and roller-skating, or in more than one branch of one or both of them, there are many ice-skaters who have no interest in or knowledge of roller-skating, and vice versa, and many keen supporters of just one branch of Skating who hardly know that the many other branches exist. It is, of course, quite possible to take part in both ice- and roller-skating, and in more than one branch of Skating, and greatly to increase one's enjoyment by doing so.

It is not particularly hard to learn to skate. It requires strong ankles, a good sense of balance, and plenty of confidence; and it is possible to start practising, at least to a limited extent, at home, for instance, by getting used to standing on skates. Skating is probably more easily mastered when young, but many adults have successfully taken it up.

Solo Whist.

Solo Whist is a card game for four players, who normally act independently. Play is as at Whist (*q.v.*), but the cards are dealt in threes, the final round being dealt singly, and the dealer exposing his last card to indicate trumps.

Players then "declare" in turn, starting with the player on the dealer's left. The lowest call is "I propose," which entails making eight tricks with a partner, any one of the other players being eligible to "accept" in his turn. The next call is "Solo," which requires five tricks to be made unassisted. Next comes "Misère," in which every trick must be lost, and then comes "Abondance," in which nine tricks must be made. Higher still is "Misère Ouverte," in which every trick must be lost with the player's hand exposed, and highest of all is "Abondance Declarée," in which every trick must be made. Any player may "Pass," and, once a call has been made, later callers must make a higher call or pass.

Though calls are made with trumps already nominated, certain calls may alter the trumps; and, with regard to these, there are several views, all quite widely held, as to the rules that should apply. A player calling Abondance can choose his own trumps, though Abondance in the nominated trumps—called Royal Abondance—takes precedence over the same call in another suit. In Abondance one school of thought holds that the first round is played on the nominated trumps, while another takes the view that the first card only is played on the nominated trumps. In either of these circumstances a player making this call should not announce his trumps until the round or card has been played, unless it is necessary to announce Royal Abondance to overcall. There is, however, a third view, and it is the view

of the majority of authorities who have actually written about the game, that the new trumps should be announced before the hand starts. Also the subject of differing views is Abondance Declarée, one view being that the caller can choose his own trumps, and another that, in this call, there are no trumps, though both views agree that this call confers the right to lead. A good player can easily adapt himself to any of these variations, the important thing being to check which versions are being used before starting to play. On the Misère calls there are no trumps, and in Misère Ouverte the player need not expose his hand until the first round has been played.

Speed-Skating. *See* **Skating.**

Squash Rackets.

Squash Rackets was designed as a preliminary preparation for the game of Rackets (*q.v.*), but it is now a popular game in its own right, played by men who have no intention of playing Rackets, and by women who never play Rackets. The game is similar to Rackets, but the court is smaller and most matches are singles. Doubles, however, can be played, and in the United States there are special doubles courts slightly larger than the normal Squash court.

Stoolball. *See* **Old English Games and Customs.**

Strand-Pulling. *See* **Weight-lifting.**

Surf Riding. *See* **Swimming.**

Swimming.

Swimming is an extremely popular pastime that also shares with walking the distinction of being a perfect exercise for health, as it exercises the whole body, and can be carried out as easily or as strenuously as the swimmer wishes. It is also a very useful accomplishment that may at any time put its possessor in a position to save a life.

There are several different swimming strokes, the basic stroke being the breast-stroke, now often seen in an alternative method, the butterfly. Faster strokes include the side-arm, the overarm, the trudgeon, and the crawl, but each of these attempts to speed up progress through the water has really superseded its predecessor, and the crawl is now almost universal. There are also two strokes used in swimming on the back, one being a back equivalent of the breast-stroke, and the other a back crawl. It is possible to swim under the water, using the breast-stroke, and to keep the eyes open while doing so. It is also possible to swim down through the water to retrieve objects that may have been dropped. Ascending through the water is automatic, though it can be hastened by a kick. Remaining stationary in deep water can be achieved either by floating on the back or by treading water, which simply means moving the legs gently up and down.

It is not difficult to teach oneself to swim, and, like cycling, it is an accomplishment which, once learned, is never forgotten. The main thing is confidence, or an absence of any fear of the water. Such fears are quite unnecessary, for water is an element that always tends to keep a human being on the surface, and not to draw him under. Going underneath the water, and staying underneath, requires a definite physical effort, and, if that effort ceases, the swimmer is automatically brought to the surface again. Many non-swimmers who get into difficulties increase these by struggling wildly, for, by doing so, they may easily take and keep themselves under. If they would make only the gentle movements of treading water, they would both stay afloat much longer and present far fewer problems to any swimmer who might be trying to save them.

Saving life in the water is the object of the Royal Life-Saving Society, which teaches the best methods of bringing people who are in difficulties ashore, and also methods of artificial respiration for use in reviving the apparently drowned. Every swimmer should acquire some knowledge of life-saving, for even a strong swimmer may experience considerable difficulty in saving anyone unless he or she has some idea of the best way of setting about it. Many swimmers, for instance, normally use only the crawl and the back crawl, whereas, to save anyone, it is almost essential to use either the breast-stroke or its back equivalent.

Swimming has a well-organised competitive side, with many competitions and championships right up to the Olympic Games. Most races take place in baths, but there are some river and sea events, and the greatest competitive challenge to any swimmer is, of course, the English Channel. Although this has been conquered many times, the swimming of it remains, and will always remain, a wonderful achievement.

Diving. Generally accepted as being akin to Swimming, though actually it is quite a different sport, is Diving. Competition Diving means using boards of various heights, performing certain set dives, and choosing additional ones from an approved list. Diving requires a certain amount of nerve, and also gymnastic ability, including the ability to control the body in the air. Whereas strong swimmers are generally fairly big, divers are often much smaller and more compactly built.

Water Polo. In view of the popularity of Swimming, it is not surprising that there is a water team game, this being Water Polo, in which the object is the scoring of goals, the ball and the goals resembling those used in Soccer, though all shots and passes are, of course, thrown. Throughout a history of nearly eighty years, Water Polo has been beset by rule trouble, and has probably been the subject of more codes of rules than almost any other game. The difficulty is the detection of fouls under the water; the ideal, a game of the basketball type, free of bodily contact.

Surf Riding. Though straightforward Swimming, Diving, and Water Polo are the chief competitive water sports, there are other water activities with large and, in some cases, growing followings, some of them also having their competitive side. Fairly old-established is the Hawaiian sport of Surf Riding, which has been seen, though generally in a rather milder form, in many parts of the world. It consists of placing a flat board on the water, and then lying, or, more rarely, kneeling or standing on it, and being carried ashore on the crest of a wave.

Water-Skiing. A growing water sport, and one in which contests are held, is Water-Skiing, which is of more recent origin than Surf Riding, from which, in fact, its development can be traced. Surf Riding led to Aquaplaning, in which the board was towed by a motor-boat, with the rider standing. A further development saw the board giving place to actual skis, and Water-Skiing was born. This sport owes some of its popularity in Britain to television, for, when still in its infancy, it was demonstrated on the screen, and this led directly to several new water-skiing centres being opened up in various parts of the country.

Underwater Swimming. Undoubtedly the fastest growing of all swimming activities is Underwater Swimming, which is a link between ordinary diving and swimming under water, with the swimmer, depending on his own lungs, able to remain below for only a few seconds, and fully-fledged deep-sea diving, with the diver weighed down with equipment and receiving assistance from the surface. The underwater swimmer receives no surface assistance, but he does use

light equipment, consisting of an artificial "lung" and breathing tubes, and also a mask and flippers. This type of swimming developed during the Second World War, in which Naval underwater swimmers, called "frogmen," rendered great services. Frogmen can also render useful services in peacetime, in, for instance, the sometimes necessary searching of rivers and canals; in underwater photography; and in exploring wrecks, and even old, lost cities, now under water. There is also a vast amount of knowledge, excitement, and pleasure to be gained from a "close-up" study of the many fascinating aspects of the underwater world.

It might be thought that the first step towards becoming an underwater expert was to become an expert swimmer, but it is not essential for an underwater swimmer to be a surface swimmer of anything like championship class. There are, of course, dangers, and the newcomer to Underwater Swimming should not go down too deep until he has had a good deal of practice and gained a certain amount of experience. Preferably, the first descents to any depth should not be undertaken alone, and if the swimmer has gone at all deep he should come up slowly, otherwise he risks getting the "bends," which is caisson disease, and means that reduced air pressure has caused nitrogen bubbles to form in the tissues. There may also be danger from large fish, and underwater swimmers should not venture into undersea caverns without a light. It is always advisable to collect as much local information as possible before diving in a strange area. Though all kinds of equipment, including cameras, harpoons, knives, and torches, can be carried, the beginner will make a better start if he dives without encumbrances. Most of the dangers can be avoided or circumvented with care, and the reward for those who master Underwater Swimming is a whole new world to explore.

Table Tennis.

Originally simply an amusing parlour game known as "Ping-Pong," Table Tennis is now a serious, world-wide, competitive sport, with many championships and tournaments, and the ability to attract crowds of 10,000 spectators.

Resembling a miniature game of Lawn Tennis (*q.v.*), the net is set on a table 9 feet long by 5 feet wide, and the ball is a very light celluloid one. Players serve series of five balls in turn, both server and receiver scoring. The service has to bounce first on the server's side of the net, and then on the other, and, thereafter, all strokes are "ground" strokes, volleying not being allowed. A game is 21 points, and matches are usually the best two out of three or three out of five games. "Vantage" games are played, as, if the score reaches 20-all, each player serves once in turn until one has a clear lead of two points. Both singles and doubles are played.

Table Tennis requires perfect fitness and split-second reactions. Many Lawn Tennis players also play Table Tennis, and several of these have found it desirable to retire from the fast table game before giving up the outdoor game.

Traditional Games and Customs.

Traditional and unusual sporting events are plentiful in many parts of the world, but few have a longer tradition behind them than the Calcio in Livrea that can still be seen, over 500 years after its inception, in the Italian city of Florence. It is a version of Football, based on an ancient Greek game called Episkuros and the old Roman game of Harpastum. Played twenty-seven-aside on a pitch rather smaller than an Association football pitch, it was originally restricted to the nobility, and in 1672 a game was cancelled when it was discovered that the selected teams included players who were only "gentlemen." The ordinary people did play, but the game as played by them was called Calcio Divisi, and was not regarded as the same thing. The playing of Calcio in Livrea faded out in 1739, but was revived in 1898, to stop again in 1902, only to be revived once more in 1930. To-day, there are generally two games a year between teams no longer restricted to the nobility and representing the four quarters of Florence. They are wonderful spectacles, for the players, and also numerous officials and attendants, wear fourteenth-century costume, and the games are preceded by ceremonial processions, and by a special address to the most distinguished person present. The trophy for the games is traditionally a white calf.

Another ancient Italian sporting event that still survives is found in Siena, and consists of horse-racing in the city. It is a wild and fierce form of racing in which virtually anything that might further the cause of victory goes on between the riders. Riding events, many of them of great antiquity, figure prominently in countries in which great horsemanship is an age-old tradition. Russia offers Kop-Karri, a fifteen-aside mounted game that is a battle for possession of a sheep's pelt. Riders carry their reins in their teeth to leave their hands free for the fight, and anyone who gets the pelt is soon downed in what is one of the roughest and toughest games of all time. Played now by Kazakhs from the Steppes and Tadjiks from the Afghanistan border, this game originated in China, and was brought out of that country by the riders of the Golden Hordes of Genghis Khan. Also found in Russia is the mounted Kissing Game, in which a galloping male horseman seeks to snatch a kiss from a girl rider armed with a whip.

Horses are also prominent in American and Canadian Rodeos, which consist of competitions and displays in the various skills appropriate to cowboys. There are riding and roping events, as well as steer-wrestling and chuck-wagon races. All the skills and dangers of the rodeo can still be seen annually in famous rodeos like that at Calgary, in Alberta. Rather different are Chilean Rodeos, in which the chief events consist of displays involving horses and young bulls, and the Topeadura, in which two mounted teams push against a long log suspended horizontally between them. Perhaps the most striking feature of a Chilean rodeo is the avoidance of anything that might harm any of the animals, which all, horses and bulls alike, seem to enter into the proceedings with excitement and enjoyment. Also including animals, but not horses, are the strange bull races held at Pamekasan in the Indonesian island of Madura. Based on the local method of ploughing, these consist of races in which a driver stands barefooted on a small wooden sled harnessed to a pair of bulls, which actually do not need much driving, the man being mainly concerned with holding on. Special attendants shield the bulls from the sun before the races, which are generally started by a veterinary surgeon.

Almost a world away from these races geographically and in everything but sheer speed is Pelota, sometimes known as Jai Alai. Played in Spain, France, Portugal, North Africa, and South and Central America, pelota is a traditional Basque game that developed from a mediæval form of handball that was played against village church walls. To this day, many pelota courts, called "canchas," are next to churches, the wall, or "fronton," which is an integral part of the game being that of the church, and the priest very often being one of the best of the local players. The game, which is very fast and exhausting, can be between two players or between teams of two or three, and consists of playing a ball that is rather smaller than a tennis ball against a wall with either the hand or, in the case of the most popular form of the game, the Grand Chistera, with a long, narrow, wicker basket, called a "chistera," that is strapped to the player's hand and arm.

Personal combat sports have always been popular, and Switzerland has a national sport of this type that had its first big tournament in 1905 in Das Schwingen, which means "The Swinging." It is a form of wrestling, in which the contestants,

normally very powerful Alpine herdsmen, wear special belts and shorts by which holds are taken. The traditional prize for the winner of the annual Swiss championship is a two-year-old heifer. Iceland has a rather similar form of wrestling, called Glima. Much less similar is the Siamese form of boxing. Competitors in this wear, and use, ordinary boxing gloves, but they are also allowed to use their elbows, knees, and feet, which are bare.

Next, a group of recreations in which the feet are used less lethally, starting with the Netherlands, and the Nijmegen Marches. Over half a century old, these are international long-distance walks that are not races, but reliability trials, in which complete teams must start and finish together within a certain time. The marches take four days, the distance to be covered each day varying between 25 and 30 miles according to the class. Classes catered for include men, women, and also police teams, walking in uniform, and military teams, carrying equipment. The walks, which attract over 10,000 competitors every July, are an unusual and colourful spectacle, and the opening ceremony is as well worth watching as that of the Olympic Games. British walkers, civilian, police, and military, regularly take part. Though called marches, they are really walks; and it is unlikely that many men would consider real precision marching as a recreation. However, women do in at least one country. This is New Zealand, where marching competitions are held between teams of twelve, with a leader, each team wearing a special uniform, and carrying out a three-minute routine to the music of a pipe band. Points are awarded, not only for the marching, but also for the costumes and the leading. Though the competitions are confined to women, teams are generally trained and drilled by men. This type of marching was seen in Britain a few years ago, when the Blair Atholl team toured the country giving demonstrations.

About fifty years old in its own country, Sweden, and quite likely to spread to other countries in the future is Orienteering, which consists of finding one's way about the country from one control point to another by using maps and compasses. Generally carried out on foot, and in wild country, it can also be done on horses, bicycles, motor-cycles, skis, and skates, and in cars and canoes, and in any kind of country, including urban areas. During the Second World War, in which Sweden, though not involved, had to be ready, Orienteering was extensively used in military and civil defence training; and it was then that night Orienteering began, with competitors wearing lamps strapped to their foreheads. Probably the most strenuous annual event in Orienteering is the Swedish three-day mountain race, in which contestants, working in teams of two, have to cover 60 miles of mountains, forests, and swamps on foot, carrying equipment that must include tents and food. Though mainly confined to Sweden, Orienteering has been successfully tried in Canada and the United States, where it acquired its English-language name.

Non-English recreations that English people do not have to travel very far to see are the many and various activities that go to make up Scotland's Highland Games. Highland Games meetings, or gatherings, are sports meetings, but sports meetings with their own definite and extremely colourful and spectacular characteristics. The chief sporting events at them are the "heavy-weight" events, including tossing the caber, throwing the hammer in the Scots style, putting and throwing weights of various sizes, and wrestling. In addition, there are competitions in Highland dancing and piping, and often for pipe bands, all playing their parts in a spectacle that can hold its own with any of the many spectacular events that love of tradition and love of sport have combined to produce all over the world. (*See also* **Old English Games and Customs.**)

Tug-of-War.

A Tug-of-War is one of the least complicated and one of the most strenuous events in sport. It consists of eight men pulling on a rope against another set of eight pulling in the opposite direction, each team trying to pull the other forward across a line, and each helped by a coach, who instructs them when to "heave" and when to concentrate on resisting the opponents' heaves. A pull may be over in a few seconds, or it may take many minutes. Contests are generally the best two out of three pulls, and a competition may involve three such contests in one afternoon. Competitions may be at "catchweights," which means that there is no weight limit, or they may restrict the eight men to a total weight of, say, 104 stone or 100 stone. The Tug-of-War requires, and will help to develop, great strength.

A popular event that always arouses great enthusiasm amongst the spectators, the Tug-of-War fully merits this position, but it owes some of its success to the fact that it was introduced into the right place at the right time. In the nineteenth century, before athletic sports were really organised, most country sports meetings included events like obstacle races, sack races, and egg-and-spoon races. These, however, though they are found to this day in some children's and local sports, grew less popular, and began to give place to more "serious" ones, a favourite replacement for them being the Tug-of-War. Then athletic sports became organised, and the Amateur Athletic Association was founded, and instituted its famous annual championships, including two Tug-of-War championships that still exist, where, a few years earlier, there might have been obstacle-race and sack-race championships.

For years, service units and police forces provided the leading Tug-of-War teams, but, more recently, they have been challenged by teams from big firms. A still later development has been the formation of clubs concentrating entirely on the Tug-of-War. Organisations and clubs with Tug-of-War teams now have their own association, and their own annual championship meeting.

Underwater Swimming. *See* Swimming.

Underwater Watching.

In recent years there has been a considerable increase of interest in the undersea world; and some participation in this has been brought within the reach of those who are unwilling or unable to take part in underwater swimming and diving by the use of glass-bottomed boats, often boats in which the viewer slides back a wooden panel at his feet to reveal the glass viewing panel. Such boats, of course, can only be of use where the water is exceptionally clear and transparent, but, where conditions are suitable, a surprising amount of the life and colour of the world beneath the seas can be seen, and without any of the strain or danger of diving.

Much of the Mediterranean Sea fulfils the necessary conditions of clarity and transparency, particularly, perhaps, the coasts of Corsica, Sardinia, Sicily, and Italy itself. Greek and Egyptian waters are also clear, as are the waters of the Spanish Costa Brava and the Balearic Islands. Going farther afield, there are very transparent waters off parts of the Australian coast, and, of course, in the West Indies.

Volleyball.

Long-established in the United States, and played also in some other countries, Volleyball is a comparatively recent arrival in Britain, where it has been encouraged by leading personalities from the sport of Athletics, who saw in it an ideal game for maintaining fitness, and formed a governing body to organise and control it. A league started in London owed much of its early success to players of nationalities other than British, but the game took a big step forward when it was adopted by the London Fire Brigade as an effective method of physical training.

Volleyball might be compared with Basketball (*q.v.*) in that it is a team game that can be played

indoors, though it can also be played on outdoor courts. The actual game, however, differs widely from Basketball. Played six-aside on a rectangular court that should not exceed 60 feet by 30 feet, it consists of "volleying" an inflated ball across a net 8 feet high with the hands, the object being to make it touch the ground in the opponents' court, while preventing it doing so in your own.

Water Skiing. *See* **Swimming.**

Walking.

Walking comes so naturally that few people ever think about it. It is, however, worth thinking about, for it is the basis, not only of everyday life, but also of every physical, as opposed to purely mental, recreation, sport, and game, all of which involve, if not actual walking, then running, which is an equally natural step beyond walking. It is also the basis of training, either for health and fitness or for a strenuous sport. It has been said that it is impossible to walk too much; and, while those who have done little walking would, of course, have to increase the distance gradually, there is no doubt that a regular, daily two- or three-mile walk would in itself prove an effective method of maintaining health and fitness.

Walking is also a pleasant recreation in its own right, in the form either of long walks or of actual walking tours, on which the walker can regulate the pace, distance, and halts to suit himself. There are different styles of walking, and some are better than others. It is, for instance, better to point the toes straight ahead, or even to turn them in slightly, as the very fit and active Red Indians did, than to turn them out. Everyone, however, has his or her own natural way of walking, and it is probably better to continue walking naturally than to set out deliberately to alter the style.

Something about the opportunities open in race walking will be found under the heading Athletics, but it might be as well to say a few words about race-walking style, and to clear up a popular fallacy. This is that race walking is unnatural, and quite remote from ordinary walking. It is not; and the fallacy has arisen largely because the walking races seen by the largest audiences are the short ones that take place in arenas during athletic meetings. An attempt to walk a short distance as fast as possible does lead to an exaggerated action, and is unnatural to the extent that anyone who really wanted to cover a limited distance as quickly as possible in ordinary life would run. The longer the distance, however, the smaller the difference between race walking and ordinary walking, competitors in, for instance, a 100-mile race being virtually indistinguishable from ordinary "hikers."

If you walk along in the ordinary way, and then try to walk faster and faster, adding to your speed by pointing the toes straight ahead, swinging the arms vigorously, and swinging the hips so that each foot falls more or less straight in front of the other, you are race walking. The official definition of race walking is so uncomplicated that it is contained in a single sentence that simply requires that contact with the ground should always be maintained, as it normally is in all walking.

Weight-lifting.

Weight-lifting is a method of exercising to maintain health and develop strength; a system of training that can usefully be at least a part of the preparation for almost any sport or game; and a highly organised and very popular competitive sport in its own right. Once, quite erroneously, thought to be an over-strenuous and "dangerous" activity, it has now, in more enlightened days, seen the pendulum swing completely in the opposite direction, with professional and amateur sportsmen of all kinds freely admitting how much they owe to it, and a large following of seekers after health and fitness, including women, many of them actresses, models, and others whose work demands a near-perfect figure.

When it is used as exercise and training, the strenuousness of it depends entirely on the wishes of the lifter or his or her adviser; for training with weights does not mean lifting as heavy a weight as possible, but carrying out a certain number of repetitions in various styles with weights well within the lifter's capacity. For those keen to develop the maximum strength of which, according to their build, they are capable, weight-lifting is certainly the quickest, and perhaps the only, way of achieving this. One of the charges levelled against it is that it makes one slow, but this is just another fallacy. It does not; and competitive weight-lifters actually make some of the fastest movements known in sport.

As a competitive sport, Weight-lifting is divided into weight classes, and there are many international and national championships and competitions. The sport is popular almost all over the world, and has been firmly established in Britain for many years.

Strand-Pulling. Akin to Weight-lifting in that it is a method of keeping fit and developing strength that is also a competitive sport is Strand-pulling, using a steel or rubber expander. Various different "pulls" are possible, and the strength and resistance of the expander can be altered at will. Many people use this old-established system of exercising for health and strength; and, for those interested, there are many strand-pulling championships and competitions.

Whist.

Whist might be called the standard card game. It has never excited quite the furore of Bridge (*q.v.*), but it is long established and popular, both at home and at Whist Drives. It is probably the first card game, apart, perhaps, from a few simple games depending on luck, that most people learn, and it provides a sound foundation for the embryo card player.

It is played by four people, two partnerships of two opposing each other, and with a normal pack of cards. The partners sit opposite each other; and the pack is shuffled, cut for trumps, and dealt out singly. The cards are then played out in thirteen tricks of four each, the player on the dealer's left having first lead, and the winner of each trick leading in the next. Ace counts as the highest card—except in cutting, when it counts as the lowest—and it is followed by king, queen, knave, and then on from ten downwards. The higher card of any suit takes the lower, unless it is trumped by a player unable to follow suit, the tricks being gathered up by the winner as made.

It is necessary to concentrate, to watch the cards played, and to endeavour to "place" the unplayed cards. This comes with experience, as does an understanding of such unwritten rules as "Second in hand plays low" and "Third in hand plays high," and a knowledge of when to disregard these.

Three-handed Whist is possible, one suit being discarded.

Winter Sports.

There are few fields of recreational or sporting activity to which, given the opportunity, British people take more eagerly than Winter Sports. Enthusiasts from Britain were going abroad to find, and in some cases start, them before the turn of the century; and to-day there are probably a hundred travellers for every one who went sixty years ago. Most of this tremendous increase has been added since the Second World War, and the numbers grow every year. Switzerland is, of course, the traditional objective, but there is

actually a wide choice, for facilities exist in Norway, Austria, Italy, France, Germany, and Czechoslovakia. There are opportunities to suit most purses, and to suit both those who want only sport and those who want sport combined with entertainment.

The most popular winter sport is Skiing; and, for those whose time and experience are both limited, it is normally skiing of the downhill variety, rather than the lengthy journeys on the level as well as on hills, and up as well as down, at which many Continental, and particularly Scandinavian, skiers are adept. Greatly increased facilities in the way of ski-lifts enable the holiday skier to work in three times as many descents as the skier of only a few years ago. Almost every resort has a ski-school with an English-speaking instructor, and it is always advisable for a novice to join this. It is also advisable for novices to start training for a ski holiday some time in advance, both by ordinary physical training and by attending a dry ski-school. The air in winter sports resorts encourages more activity than is good for a completely untrained person, and the fitter the skier, the less his chance of being injured. Skiing accidents are plentiful, but many of them could be avoided by the exercise of a few simple precautions. Having lessons is one; being fit is another; short skis with safety bindings are still another; and refusing to ski late, which may be any time after four o'clock, is yet another, for, as the light fades, it is replaced by a bluish light that makes uneven patches difficult to see, and the snow tends to ice over. Most winter sports equipment can be hired, but hired or bought, and regardless of the extent to which fashionable skiing clothing may be advertised, the most important items are the boots. The winter sports season lasts from December until March, but the snow is sometimes late, and, while Christmas and New Year should be safe enough, February offers the certainty of snow, combined with longer days.

Ski-jumping is a separate sport, and one for experts. The jumper takes-off down a steep slope and over a platform, which he leaves at a speed of about 50 m.p.h., to land something like 150 feet below his take-off, and more than that distance out in front of it. Ski-Joring is really ski-racing behind unridden horses, but the term is also applied to quite gentle ski-trips behind ridden horses, horse-drawn vehicles, and mechanical vehicles.

Bobsleigh Riding and Tobogganing consist of riding and racing down ice runs at terrific speeds on sleighs, the bobsleigh being for two, four, or five riders, and the toboggan, which takes its name, not from anywhere in Europe, but from a Red Indian language, being for one rider. Bobsleigh crews sit, the first man steering by a wheel or ropes, and the last man operating the brake with which the sleigh is fitted. Toboggan riders lie face downwards, and brake through special spikes on their boots. Both sports are exceptionally thrilling, and both can be dangerous.

At the opposite extreme from the point of view of speed is the 400-year-old Scottish game of Curling, which is played on ice, but not on skates. It resembles Bowls (*q.v.*), but the implements used are curling stones weighing about 35 lb., and having handles. Slow, but still-moving stones are encouraged by sweeping the ice in front of them with brooms.

Not a European winter sport, but nevertheless a snow sport in Canada is Snowshoe Running. Like skiing, this is a useful method of travelling about on snow that has been made the subject of races. The Canadian side of the Atlantic is also the home of Snow Snakes, a Red Indian game that consists of throwing a polished wooden stick along an ice trough in the snow. These "snakes" have been known to go for over a mile and to travel at 120 m.p.h. (*See also* **Skating.**)

Wingfield Sculls. *See* **Boat Races.**

Wrestling.

Wrestling, an individual combat in which competitors, using only their bare hands, endeavour to throw each other, is one of the most natural sports, and also one of the oldest. It is practised in many countries, and in many different styles, in most of which the wrestlers are divided into classes by weight.

In Britain, probably the most popular style is Catch-As-Catch-Can, in which the wrestlers start apart, and may try to throw their opponents by grasping them with the hands or by various kinds of trip. During the bout, the competitors may be either on their feet or down on the mat, and the rules contain various provisions to prevent the bout lasting for an indefinite time. Wrestlers reaching a deadlock on the mat may be ordered to stand up and start again, and points decisions after a certain time are also possible. Certain dangerous holds are barred.

Another style is Cumberland and Westmorland Wrestling, which is extremely popular in those counties, and in Scotland. In this, the wrestler clasps his hands together behind his opponent's back, and all throwing is done by the legs, the breaking of the opponent's clasp constituting the fall. The initial hold is, therefore, of major importance, and the taking of it often takes longer than the actual bout.

A further form of British wrestling is Cornish Wrestling, in which the wrestlers wear canvas jackets, by which all holds are taken. A similar form of wrestling is found in Brittany.

In Græco-Roman Wrestling, which has always been very popular on the Continent, though less so in Britain, wrestlers start apart, and may take hold only above the waist. Bouts in this style may take a considerable time. At one time, there were many Græco-Roman handicap matches, in which a top-class wrestler undertook to win a fall, or a number of falls, in a fixed time.

Græco-Roman was formerly the style used in professional wrestling, but, in recent years, professionals have used the 'Free" or "All-In" style. This has rules, but it is not always very clear just what they are, and this, combined with widespread suspicions that bouts are not really genuine contests, has led to the quite large following that it retains going to see it more as an amusing "stunt" than as a serious sporting event. In the United States efforts to widen interest in it have taken the form of staging bouts in a ring that has been turned into a sea of mud, or that has been filled with fish. All this has, of course, done considerable harm to the reputation of what is really a fine sport and a healthy exercise.

Judo. Prominent amongst countries in which Wrestling has been popular for centuries are Oriental countries such as India, China, and Japan. There are various styles, and one of the two main Japanese styles has won popularity in many countries, including Britain.

This is Judo, sometimes, less correctly, called Ju-Jitsu. Governed largely by traditional rituals, and with wrestlers divided into different grades according to ability, Judo is now an international competitive sport; but it is more often taken up as an effective method of self-defence against a stronger or better-armed attacker. Requiring deep study and a thorough knowledge of anatomy, but not a particularly strong physique, it consists partly of defence by knowing how to sustain bad falls without injury, and partly of attack by locks which give the opponent a choice between capitulation and a broken bone, and by paralysing nerve centres. The various locks are potentially highly dangerous and, when practising, should always be released the moment the opponent requests this.

Radio, Television and Radar

TABLE OF CONTENTS

Radio, Television and Radar

By T. W. BENNINGTON and M. G. FOSTER, A.M.I.E.E.
(Engineering Division, B.B.C.)

RADIO.

Historical.—Though it is not possible to ascribe the "invention" of radio to any one man, it is true to say that its discovery and subsequent development as a means of communication was primarily due to the work of three. Between them—not, of course, together—these three conceived the idea of wave motion through space, of its use as a means of communication, explained and proved the physical processes involved, and brought the idea to practical fruition.

The theory of electromagnetic waves—of which the radio wave is one—was originated by the British physicist James Clerk Maxwell in 1864. He formulated a set of equations which have become famous as the basis of the behaviour of electromagnetic waves in space. These showed that both electrical and optical phenomena in space are essentially similar in character, and that the waves if short in wavelength are those of light, whilst if of longer wavelength they are radio waves. Maxwell was never, in his own lifetime, to see such waves actually produced by electrical means, yet by his purely mathematical investigations he laid the foundation upon which the art of radio communication was to be built.

When Heinrich Hertz—the second member of the trio—succeeded in 1888 in producing such waves by electrical means he found them to conform to Maxwell's theories in every particular. Although Hertz's work was purely in the nature of laboratory experiments, he made many useful discoveries about the waves themselves, and about their behaviour under differing conditions, and also about the apparatus necessary for producing them.

It fell to Marconi to develop the use of radio waves as a practical means of communication. He came to England in 1896 after carrying out his early experiments in his native Italy, and a British patent for his apparatus was at once granted. Encouraged by the sympathetic interest of the British Post Office, Marconi soon succeeded in establishing communication between Penarth and Weston-super-Mare. Following this achievement, he rapidly effected improvements in the apparatus, which increased its range. In 1897 the first Wireless Signalling Company was formed, and in 1898 the first two paid wireless messages were sent, in this country. By 1900 Marconi had amply demonstrated that communication by radio was a commercial proposition, and radio stations for regular operation on ship and shore were being built.

In 1901 Marconi went to America, there to attempt the reception of radio signals sent out by his station at Poldhu in Cornwall. And on 12th December, 1901—after innumerable difficulties had been encountered and overcome—the famous "S" signals of the Morse code sent out from Poldhu were received in Newfoundland, thus proving that radio waves could pass from the Old World to the New, and—most important discovery of all—could bend around the spherically shaped earth.

It was not easy to explain this point at first, for it was part of the theory that radio waves—like those of light—must, so long as they travelled constantly in a medium like air, move in straight lines. Some slight "bending" or diffraction over the horizon was understandable, but this was insufficient to account for the waves reaching Newfoundland. Then, almost simultaneously the British physicist Oliver Heaviside and the American Dr. A. E. Kennelly came forward with an explanation. They suggested that the air in the upper atmosphere had different electrical properties from that lower down. It was not, like the latter, an electrical insulator, but a conductor, and as such had the property of "refracting" the waves, and so of causing them to curve round in the upper atmosphere so that they returned to earth at a far distant point, thus enabling them to travel round the spherically shaped earth. The Kenelley-Heaviside "layer" theory was soon accepted by the world of science because it explained known facts about the behaviour of radio waves, though it was not until 1925 that the British scientist Sir Edward Appleton first determined the actual position of the layer in the atmosphere.

In the meantime the art of radio communication had progressed by leaps and bounds. Many scientists and inventors, both in this country and abroad, had contributed to this rapid advance, but perhaps the most far-reaching contribution of all was the invention of the radio valve by Sir Ambrose Fleming in 1904. This—one of the most remarkable of all man's inventions—was destined not only to revolutionise radio telegraphy but also to solve the problems which had so far prevented the successful development of radiotelephony, and eventually to make possible the transmission of high-quality speech, music, and even vision signals, and thus lead to broadcasting and television.

Although one of its most useful applications has always been as a means of communicating with ships at sea, radio has spread to so many other fields that to-day the whole world is closely linked by a vast and complicated network of radio communications. The broadcasting of news and entertainment—which began in this country in 1920—is now an almost essential part of normal civilised life, the transmission of still pictures and of living scenes is rapidly becoming so, whilst radar has brought about startling changes in marine and aerial navigation. In little more than half a lifetime the experimental toy of a young inventor has developed into a practically indispensable amenity of everyday life.

A complete understanding of radio can be acquired only by long study of the electrical and scientific facts and principles involved, but in the notes which follow we shall endeavour to give an insight into some aspects of radio communication and into the general working of some of the apparatus in as simple and non-technical a way as is possible.

Radio Waves and How They Travel.—When an electric charge is oscillating along a radio transmitting aerial it produces both an electric strain and a magnetic strain in the surrounding space and these two forces act at right angles to each other. At the conclusion of each oscillation the two strains are "broken off" and lose their contact with the aerial. The resultant disturbance in space constitutes an electromagnetic or radio wave. These waves do not require any material medium to support them—they can exist equally well in a vacuum. Thus we may discard the old conception of an "Aether" in which radio waves were once thought to travel. The waves travel through space with a velocity of 186,000 miles or 300 million metres per second. They travel through ordinary air at the same rate, but if they enter a medium with different electrical properties from those of air their velocity is altered.

We have seen that one complete wave leaves the aerial for each complete oscillation of the electric charge, and thus it is obvious that their rate of emission depends on the "frequency" of the electric oscillations being generated by the radio transmitter. If the charge be oscillating up and down the aerial 300 million times per second the frequency will be 300 million "cycles" per second. At the end of one second the front of the first wave

will be 300 million metres away from the aerial—since the waves travel that distance in that time—whilst the last wave will just be leaving it. Three hundred million waves will, therefore, occupy the listance between the first wave front and the aerial, and thus the distance occupied by each wave, *i.e.* the "wavelength" will be 1 metre. If the charge is now made to oscillate 100 times more slowly than before—at a frequency of 3 million cycles per second—then at the end of one second there will only be 3 million waves occupying the 300 million metres of space. The wavelength will therefore be 100 metres. Thus a wave of low frequency has a long wavelength, whilst a high-frequency wave has a short wavelength. To obtain the relation between the two quantities it is only necessary to remember that Wavelength (in metres) equals Velocity (in metres per second) divided by Frequency (in cycles per second). Radio waves range in length from about 30,000 metres at the long-wave end to less than a centimetre in the case of the shortest waves.

a partial conductor—a property imparted to it by the action of the sun.

On entering the ionosphere the velocity of the wave is changed and, instead of continuing in a straight line, it is gradually turned round and eventually directed downwards again towards the earth. Successive reflections of the wave between the ionosphere and the earth enable it to travel great distances in a series of "hops," as indicated in Fig. 1.

Now the action of the ionosphere upon the waves varies, not only with the time of day and season, but also with wavelength. Medium waves are not reflected—at least not during the day—but are lost within the ionosphere, hence their range depends on that of the ground wave. At night, however, some reflection does take place, and that is why—for example—distant medium-wave broadcasting stations may sometimes be heard at night and not during daylight. It is their "sky" wave and not their normal ground wave which reaches the longer distance. In the case of the

TABLE I

Class.	Wavelength Range, Metres.	Main Characteristics.	Principal Uses.
Long Waves.	Above 1,000	Travel long distances over earth's surface, also to greater distances by reflection from ionosphere.	Navigational aids, medium and long-distance point-to-point communication "National" broadcasting.
Medium Waves.	1,000 to 100	Travel over earth's surface only during the day, some reflection from ionosphere at night. Only medium-distance range during day, somewhat greater at night.	"National" broadcasting marine and aircraft communication, direction finding.
Short Waves.	100 to 10	Travel up to ionosphere, then back to earth. Conditions for ionosphere reflection vary with time of day and season. Very great distance range.	Long-distance "international" broadcasting, point-to-point communication, etc.
Very Short, Ultra Short, Super Short, and Extremely Short Waves.	Below 10	Travel just above and over earth's surface only, and for relatively short distances.	Short-distance communication, v.h.f. broadcasting, television, radar systems, etc.*

* A recent development, whereby the radio energy which is "scattered" at certain levels in the atmosphere is utilised, has extended the range of Very Short Waves to about 1,400 miles, and Ultra Short Waves to about 200 miles. Transmission in the former range is at present limited to telegraphy and telephony communication, whilst the latter is still in the experimental stage.

Although there is no difference in the *nature* of radio waves of differing wavelength, their actual behaviour during transmission varies tremendously according to their wavelength. In particular, their distance range varies greatly, and thus waves of different length are suitable for different purposes. Table I above *roughly* classifies them according to their wavelength, and indicates the purpose for which they are used.

The reasons for the variation in the distances reached by waves of different wavelength are briefly as follows: We will assume that the transmitting aerial will radiate waves in all horizontal and vertical directions. Let us consider first the horizontally radiated energy, which, because it travels close to the earth's surface, is known as the "ground wave." As the ground wave travels along some of its energy is absorbed by the earth itself, and so the wave is weakened and soon tends to die away. The *amount* of energy so lost increases as the wavelength decreases. Long waves lose relatively little energy in this way, and so their distance range is great. As the wavelength is decreased through the medium waveband the ground losses increase and the waves die away more rapidly, having only a medium distance range, whilst when the short waves are reached the range is reduced to a few tens of miles.

The waves travelling upwards from the aerial go on until they reach the atmospheric region known as the "ionosphere," which lies between about 60 and about 300 miles above the earth's surface. In this region the air is not an electrical insulator but

short waves the ionosphere normally acts as an efficient reflector of the upward-travelling waves—the precise manner depending on ionospheric conditions at the time—so the "sky" waves are returned to earth at all times, and consequently reach to great distances. These short waves are therefore most suitable for really long-distance communication of all kinds. Below a certain wavelength, however, the ionosphere no longer

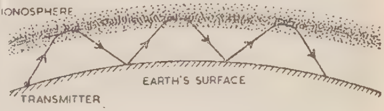

FIG. 1.—WAVE TRAVELLING IN HOPS BETWEEN EARTH AND IONOSPHERE.

acts as a reflector, and these very short waves normally pass right through it. The distance range is therefore that of the ground wave, and so is relatively small. Recently, however, it has been found possible to achieve ranges of about 1,400 miles on the Very Short Waves and 200 miles on the Ultra Short Waves by making use of the "scattering" of radio energy which occurs at certain levels in the atmosphere. This type of transmission is not as yet much beyond the experimental stage.

Wavelengths for Broadcasting.—So far as broadcasting is concerned, therefore, it will be seen that, for "international" or long-distance broadcasting, there is no choice but to operate on the short waves (high frequencies), because it is only on these wavelengths that the sky-wave will be efficiently propagated by the ionosphere so as to travel the great distances required. The overseas services of the B.B.C., for example, are provided upon various "bands" of short wavelengths, these bands being altered to suit the time of day, season of the year, and direction and distance of the target area. Similarly, television services are, perforce, conducted on the very-short or ultra-short waves (very-high or ultra-high frequencies) because the nature of the transmitted material requires a very large band-width for successful transmission, and such large band-widths can only be provided on these, or even shorter wavelengths.

So far as short-distance, or "national," sound broadcasting is concerned, this has, in the past, been carried out upon the long and medium waves internationally allocated for this purpose. But for some years past the demand for these wavelengths has been greater than the supply, *i.e.*, the number of broadcasting stations has increased until there is no longer room for the proper inclusion of their transmissions within the available wavelengths. The result has been such overcrowding and congestion of stations that reception, in many cases, is no longer technically satisfactory, *i.e.*, the radiations from one station produce interference in the form of "whistles" or "chatter" on the programme of another whose allocated wavelength is near its own. Particularly is this so after sunset, when, as already explained, the sky-waves of medium-wave stations travel long distances and so cause interference in areas where they are not heard during the daytime. Short of closing down numbers of these stations altogether (a project which has not been found possible), the only solution to the problem is to conduct the national broadcasting services on wavelengths which are not subject to such interference.

The very short wavelengths (very high frequencies) are the most satisfactory for this purpose mainly because, on these wavelengths, the sky-wave is not reflected by the ionosphere at night, and so does not travel outside the proper service area of the station and cause interference to other stations.

Since 1955, therefore, whilst still retaining the long- and medium-wave transmissions, the B.B.C. has been developing its very high frequency (v.h.f.) sound broadcasting service on wavelengths of the order of 3 metres (frequencies from 88 to 95 Mc/s.) until at the present time (Autumn 1959) the Home, Light, and Third Programmes, together with Network Three, are available on these frequencies to approximately 97% of the population of the United Kingdom. These services also make use of an improved system for modulating the transmitted wave with the programme impulses, known as frequency modulation (f.m.), and thus these transmissions give improved fidelity, much greater freedom from interference and a larger area of satisfactory broadcast service than could be given by a comparable amplitude modified (a.m.) transmitter on the medium waves.

It should be added that under certain ionospheric conditions, such as those occurring near the maximum of the sunspot cycle, a certain amount of interference to the v.h.f. and television services can occur from distant stations during the daytime, principally in those areas where the signal is weak, or in cases where inefficient aerials are used.

Broadcasting.—The technical problems involved in broadcast transmission and reception may be summarised as follows: to convert the sound waves of the programme into electric impulses or currents, each characteristic of the sound itself; to convey these impulses without distortion to a radio transmitting station; to superimpose them on the electromagnetic waves being radiated so that they are diffused into space; to pick the waves up again at a distant point and to separate the electrical impulses from them in their original form; to increase them in magnitude in order to compensate for the losses during transmission, and, finally, to reconvert the impulses into sound waves of a similar nature to those originally produced.

Sound waves are set up in the air in the broadcast studio when any "noise"—musical or otherwise—is made, these air disturbances travelling outward from their source at approximately 1,100 feet per second. The character of a sound wave varies in accordance with a number of factors, one of which is its "frequency." If the number of air vibrations per second is large the "pitch" of the note is high, whilst if it is small a low note is produced. The lowest note of a piano, for example, has a frequency of 27·5 cycles per second, and its highest note about 5,600 cycles per second. The range of frequencies which the average person can appreciate is from about 20 to 16,000 cycles per second. A second feature possessed by a sound is its "loudness," which depends upon the *intensity* of the sound waves produced, whilst a third and more subtle characteristic is the "sound quality." It is this which enables us to distinguish between two sounds of the same pitch and loudness, and to recognise, from the distinctive quality, to which instrument of the orchestra each owes its origin. This quality of a sound is due to the fact that it consists, not of a single frequency, but of a mixture of one "fundamental" frequency and several "harmonics." The proportion in which these harmonics are present determines the musical quality or "timbre" of a note or sound.

In broadcasting the aim is to transmit all these features of the sounds without distortion. Al though this cannot be done perfectly—because the apparatus is unable to handle the full ranges of frequency or loudness—good-quality transmission can be achieved if frequencies from about 30 to 10,000 cycles per second, and a loudness range covering all but the weakest and most intense sounds, are provided for.

Broadcast studios are rooms designed to suit a particular type and size of programme, the walls—which both reflect and absorb the sound waves—being constructed or treated so as to give tha quality to the sounds most desirable and pleasing for the particular type of programme. In addition, there are "General Purpose" studios, whose acoustic characteristics can be varied to suit the programme requirements. Adjacent to the studi there is usually a listening-room, sound insulated from the studio, in which the programme can be heard from a loudspeaker, so that it may be judged as it will sound in a listener's home, as distinct from what it sounds like in the studio. Sometimes it is necessary to add "echo" to the programme, *i.e.*, to give an effect such as would be produced in the interior of a cathedral. This is achieved by taking part of the studio output to a loudspeaker in an "echo room." The sound from this goes echoing round the bare walls of the room and the result—containing the echo—is picked up by a microphone, and may then be added to the original programme.

Each studio contains one or perhaps several microphones, according to the purpose for which it is used, these being the devices which convert the sound waves into electrical impulses. The type of microphone in most common use to-day is the "ribbon" type, in which a strip of aluminium foil is suspended within a strong magnetic field. Any movement of a conductor in a magnetic field causes an electrical voltage to be set up in th conductor, and when the aluminium "ribbon" vibrates under the impact of the sound waves electrical voltages or impulses are set up in i which are faithfully representative of the sound which caused them. The outputs from severa microphones may be mixed in any desired propor tion by means of a simple electrical arrangemen in the listening-room, and the combined output then taken to the control room of the broadcastin centre.

The control room is the electrical "nerv centre" of the whole system, and through it all th programmes pass. It contains "amplifiers" t which the studio outputs are connected, "mixers for combining, when necessary, the outputs of several studios or other programme sources, an switching arrangements and "fade units" fo maintaining the continuity of the programm This equipment is followed by the main contr amplifier and the control potentiometer, by mea of which the intensity of the electrical impulse kept within the range that can be handled b

subsequent apparatus. Finally, there are the amplifiers which transfer the programme to the lines connecting the control room to the radio transmitters.

When the programme originates at an outside point—like a sporting event—apparatus is taken out to the programme site itself, comprising microphones, amplifiers, mixers, and control units, together with means for communicating to the nearest broadcasting centre. The "outside broadcast" is controlled and amplified "on site" and then sent to the control room, where it is fitted into the main programme as if it were from one of the local studios.

No matter where the programme originates, it is eventually sent along the lines connecting the broadcast centre to the radio transmitters, and in this process the impulses soon become weakened by the losses to which they are subject. At intervals of about 40 miles, therefore, a special amplifier, known as a "repeater," is inserted into the lines in order to restore them to a workable level. Arrived at the transmitter, it is found that the high frequencies—corresponding to the high notes of the programme—have become weakened to a greater extent than have the low ones, and in consequence the programme is very much distorted. It is, therefore, passed through an "equaliser" which weakens all the impulses in inverse proportion to their frequency, and thus the distortion introduced by the lines is removed. It is then only necessary to pass them through an amplifier which increases all the frequencies equally and so bring the programme back to a volume suitable for feeding to the transmitter itself.

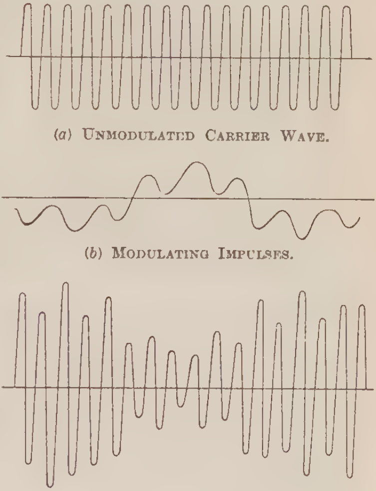
Radio Transmitters.—The first function of a radio transmitter is to generate high-frequency oscillations which, when amplified and fed to an aerial system, will set up electromagnetic waves in space. Its second is to provide some means of "modulating" these waves so that they will carry the intelligence which it is desired to transmit.

The transmitter may operate upon wavelengths varying from several thousand metres to a few centimetres (*i.e.*, the frequency of the oscillations it produces may vary from a few thousand cycles to hundreds of millions of cycles per second) according to the purpose for which it is intended. The form of intelligence transmitted may also vary widely, ranging from telegraphy to broadcast speech and music or television.

In the course of their development radio transmitters have employed many different systems of generating the high-frequency oscillations. Among these may be mentioned the induction coil, the spark transmitter, the Poulsen arc, and the high-frequency alternating voltage generator. All these systems, however, have disadvantages which are not shared by the thermionic valve, and consequently this has gradually superseded them and is now almost exclusively the means used to generate the oscillations in modern radio transmitters.

If a coil of wire is connected in the anode circuit of a valve, and another coil in the grid circuit, the valve can, by means of the electrical interaction between these coils, be made to produce electrical oscillations. By choosing particular values of "inductance" and "capacity" in these circuits the oscillations can be "tuned" to the desired frequency. The "inductance" usually consists of suitably proportioned coils of wire, whilst the "capacity" is provided by means of "condensers," which consist of sheets of metal separated by air or some other insulating material.

Such a circuit, however, exhibits a tendency to change its operating frequency slightly with small changes in the voltages supplied to the valve, and changes in the temperature of the air surrounding the oscillatory circuit. Such changes would, of course, alter the operating frequency, and thus the wavelength, of the transmitter, and, as this is obviously undesirable, steps are taken to control the circuit in such a way as to prevent these changes occurring. Firstly, the oscillatory circuit is usually supplied through a voltage regulator which keeps the voltage nearly constant, despite variations in the voltage incoming to the regulator itself, and it is placed in a small oven whose temperature is maintained constant within very close limits by means of a thermostat; secondly, "crystal control" is applied to the oscillator. Certain crystals such as natural quartz, Tourmaline, Rochelle salt, etc., possess what are known as "Piezo-electric" properties. Very simply, if subjected to mechanical compression or tension these crystals produce an electrical potential difference across certain axes. Conversely, if an alternating voltage is applied to the crystal it will vibrate, and if the frequency of the alternating voltage is close to the natural frequency of the crystal—which is determined largely by its physical dimensions—something approaching mechanical resonance occurs. This mechanical vibration sets up a correspondingly large oscillatory voltage across the crystal, which is applied to a valve and used to maintain the electrical oscillations in the valve and its associated circuit. Since the frequency of oscillation is almost entirely governed by the dimensions of the crystal, a very high degree of transmitter frequency stability can be achieved by using a crystal in this way. The oscillations which are produced by this "drive" circuit (as it is called) are then passed through as many "amplifying" stages as are necessary to increase



(*a*) Unmodulated Carrier Wave.

(*b*) Modulating Impulses.

(*c*) Amplitude-modulated Wave.

Fig. 2.

the power to a level suitable for applying to the aerial. Such oscillations when radiated by the aerial do not themselves convey any intelligence, and the resultant wave is called the "carrier" wave.

To impart the intelligence to the carrier it is necessary to "modulate" this wave with, for example, a broadcast programme. This, as we have seen, is composed of electrical impulses which vary in accordance with the sounds which produced them. Like the output of the drive circuit, the programme signals received over the lines from the studio are amplified until they are of sufficient power to be applied to the modulator valve or modulation transformer, according to the system in use in the particular transmitter. By one of these means these amplified programme currents are made to alter the "amplitude" of the oscillations of the carrier wave. The result is that while the *frequency* of the carrier wave is unaffected, its *amplitude* varies in sympathy with the programme impulses it is carrying. The programme impulses are therefore conveyed through space to the receiver, and at the receiver it is only necessary to cause the *variations* in the amplitude of the received wave to set up electric currents, and these will be an exact replica of those produced by the microphone. Fig. 2 will help to

explain the process of modulation; it shows in diagrammatic form: (*a*) the unmodulated carrier wave; (*b*) the programme impulses; and (*c*) the modulated carrier. The method described above is only one way of modulating a carrier wave, though such *amplitude-modulation* (a.m.) is still the most widely used system for broadcast transmission. However, another rather more complex method, known as *frequency modulation* (f m.), has certain advantages, and is being used both in this country and abroad; in particular, in the v.h.f. sound-broadcasting services of the B.B.C. In this system the *amplitude* of the carrier wave remains unchanged and the programme impulses are caused to vary its *frequency* at a rate corresponding to the pitch and loudness of the programme sounds. See Fig. 3. Under suitable conditions a transmitter using this system can give improved fidelity of reception, greater freedom from interference, and a larger broadcast service area than a comparable amplitude modulated transmitter.

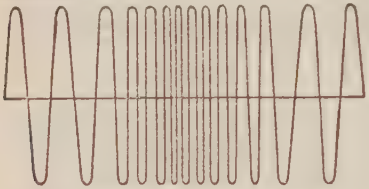


FIG. 3.—FREQUENCY-MODULATED WAVE

The modern high-power transmitting station is an elaborate and complicated plant occupying—with its associated masts and aerial systems—many acres of ground Nowadays most stations draw their power from the public electricity-supply mains, although frequently stand-by generating plant is installed (and in some instances very large-capacity storage batteries from which power can be drawn for limited periods) for use in the event of a breakdown.

Power from the mains (or the station's own generating plant) is fed either to motor-generator sets or to transformers and rectifiers, which produce the necessary voltages for operating the transmitters. The "high-tension" supply for a medium-power transmitter is often of the order of 15,000–20,000 volts, nearly one hundred times that of the ordinary domestic lighting mains! Most up-to-date stations have a control desk from which the filament, grid bias, high-tension, and other supplies are controlled, and on which are duplicated all the voltmeters, ammeters, and other instruments necessary to inform the control engineer of the operating conditions of the transmitter itself.

In the early (low-power) stages the valves are cooled by normal heat radiation in the same way as a receiving valve, but as the power handled by the valves increases it is necessary to provide a blast of air or to use water-cooling to carry away the waste heat. The cooling air is drawn from outside, filtered and blown round the valves through ducts specially designed to direct the air where it is most needed (in some instances the air after being heated by its passage over the valves can be used to warm the station building in cold weather). When water-cooled valves are used the water is circulated through water-jackets round the valve anodes. All the coils, condensers, resistances, and other components associated with the valves are enclosed with them in glass-fronted steel cubicles, the doors of which are interlocked in such a way as to prevent the high voltages being switched on when the doors are open or, alternatively, to switch them off if the doors are accidentally opened while the transmitter is working. This arrangement and other more complicated interlock schemes protect both the engineers operating the station and the equipment itself from accident.

Adjacent to the transmitter and its control desk there is usually a small control room which houses the amplifiers and equalisers associated with the lines bringing the programme from the studios. It is here that the necessary adjustments, described earlier, are carried out before the programme is passed to the transmitter proper.

Individual transmitters may vary very much in detail from the above description, since there are so many different varieties, long-, medium-, short-, or very-short-wave transmitters; some used solely for radio-telegraphy, others for long-distance radio-telephony, for communication with ships at sea, for broadcasting, for television, for radar, and for other purposes.

Some broadcast transmitters are automatic. They are switched on and off by a time switch, and whilst in operation are monitored by automatic equipment which will call attention to any faults which may develop by ringing an alarm at the nearest manned station. In addition, the automatic monitor can, in certain circumstances, change over, or switch off, defective items of equipment without interrupting the service. More and more B.B.C. stations, particularly those used for the v.h.f. f.m. sound broadcasting service, are being built for unattended, automatic operation.

Aerials.—The function of the aerial is to place the high-frequency oscillations generated in the transmitter in contact with as great a volume of space as possible, so as to permit a relatively large radiation of energy into space. Conversely, a receiving aerial, because it is in contact with a comparatively large volume of space, can absorb a larger amount of energy from the passing wave than the receiver circuits themselves. All radio receivers—except those fitted with a built-in "frame" aerial—should therefore be connected to an efficient aerial in order to obtain the best results.

Transmitting aerials vary considerably in design and construction, according to the wavelengths upon which they are intended to operate and the degree of directivity which it is desired to achieve.

Medium-wave aerials generally consist of an earthed vertical radiator a quarter of a wavelength long, this being the best condition for efficient radiation with such an aerial. Sometimes a horizontal "roof" is added to the vertical part, and a "loading coil" is usually provided by means of which the aerial may be "tuned" over a range of wavelengths. By using more than one vertical aerial it is possible to direct the radiated energy towards a particular area, but the effect is limited. In recent years "mast-radiators" have come into use in increasing numbers. In an aerial of this type the mast itself is mounted upon insulators, and the steelwork used for its construction becomes the radiating system. Such an arrangement is not only economical but also possesses other advantages. For example, by fitting a "capacity top"—a series of arms similar in appearance to the ribs of an umbrella—the electrical characteristics of the aerial, in particular its effective height, may be altered. Thus the aerial may be tuned, and in certain circumstances the shape of its service area can be slightly adjusted, which is sometimes very valuable, particularly in the case of aerials being used for broadcast transmission. Mast radiators are sometimes divided into two parts by an additional insulator inserted into the structure at a chosen height. By feeding the output of the transmitter to the two sections of the mast separately—usually at their junction—the effect is that of an elevated half-wave aerial, and it can be adjusted to extend the fading-free range of the station.

Short-wave aerials are usually unearthed horizontal lengths of wire, half a wavelength long, connected to the transmitter by feeder lines so arranged as to have no effect on the wavelength. Short radio waves are easily "beamed," that is to say they lend themselves to transmission in specific directions. In long-distance transmission this is generally desirable, and it is achieved by increasing the radiated energy in certain directions and suppressing it in others. The energy is concentrated not only in azimuthal directions, but, so that it may reach only the desired reflecting point in the ionosphere, in vertical directions as well. This is usually done by using an aerial "array" consisting of a number of half-wave aerials arranged in rows, in both the horizontal and vertical planes; in general, the greater the number of aerial elements there are, the narrower can the beam be made in both planes. The vertical angle in which the beam is projected is controlled by the

height at which the array is suspended above the ground.

In order to suppress the energy in unwanted directions a "reflector curtain" is hung behind the main array and spaced a quarter of a wavelength from it. This "curtain" consists of a similar arrangement of half-wave aerials, but it is not fed with energy from the transmitter. If it is desired to transmit at different times to places lying in opposite directions, special switching facilities are often provided for the arrays. These are so arranged that when a particular aerial has finished transmitting in, say, a northerly direction, it can serve as a reflector for the aerial working in a southerly direction, which had previously acted as a reflector for the north-bound transmission. By such means economies can be effected in the use of materials and ground space.

There are several other varieties of short-wave aerials available, and the precise type to be used for any project is largely dictated by the particular purpose for which it is required and any special circumstances which may be involved.

For television and other ultra-short-wave transmissions it is also usual to employ half-wave aerials, but in these cases the wavelengths are such that rigid conductors may be used. The most important single factor to be considered in this wave range is the height of the aerials above the ground. They should be as high as practicable, as, at these very high frequencies, the waves travel directly through the lower atmosphere, and the greater the height of the aerial the greater the distance range of the transmissions. The most common aerial used in this wave band is the half-wave dipole, which is frequently constructed from rods or tubes, although some transmitting aerials are made from heavy metal strips. For receiving, a rigid vertical rod with a reflector behind it—the familiar "H" aerial—is most commonly used, and increased "gain" in the direction desired is often achieved by the fitting of additional elements in front of the receiving aerial itself. Yet another type of transmitting aerial, suitable for use at very high frequencies, is known as the "slot aerial," and consists of one or more narrow rectangular apertures half a wavelength long in an electrically conductive sheet. In practice, the slots are usually arranged round the periphery of a vertical metal cylinder so as to give a uniform signal in all directions. Each slot is energised by a vertical rod placed just behind it inside the cylinder and connected to the transmitter by a co-axial feeder Since the actual slot may be filled with an insulating material, such as Perspex, an aerial of this type can readily be made weather-proof, and the mechanical construction is relatively simple. Aerials of this type are used at most of the B.B.C.'s v.h.f. f.m. sound broadcasting stations.

Radio Receivers.—Although the broadcast receiver is only one of the many types of radio-receiving equipment in everyday use, the general principles underlying its operation are common to all radio-receiving apparatus.

As stated earlier, its main functions are to accept the energy picked up by the aerial from the passing radio waves; to separate the low-frequency programme impulses from the high-frequency carrier wave; and, having separated them, to amplify these programme impulses to a power level sufficient to operate the subsequent apparatus, usually a loudspeaker, for reconversion into sound.

Tuning the Receiver.—In order that the receiver may respond to the waves sent out by the station it is desired to listen to, and not to those of stations operating on other wavelengths, means must be provided to adjust it to accept signals of one wavelength, and to reject the others. This process is called "tuning" and makes use of the principle of "resonance."

When travelling by bus it is frequently noticed that at a certain speed a particular window will commence to rattle violently; above or below that speed the window is quiet. This phenomenon is caused by mechanical resonance. The window—due to its shape and size and the physical properties of the materials of which it is made—possesses a certain natural frequency of vibration. When the engine of the bus is running at the speed which sets up vibrations in the vehicle at or very near that natural frequency, the window starts to vibrate in sympathy. Now in electrical circuits which are made up of inductance and capacity each individual circuit has a resonant frequency. At this particular frequency the circuit will pass its maximum current, and, like the bus window, if it is "excited," this time by electrical oscillations at or very near that resonant frequency, it will respond readily, whereas it will be almost unaffected by oscillations of a different frequency. In the radio receiver therefore it is arranged, by the process of "tuning," to alter the resonant frequency of the circuit to which the oscillations picked up by the aerial are fed. This alteration can be achieved either by changing the number of turns of wire on the tuning inductance, or by altering the capacity of the tuning condenser, or both. In practice, it is not very convenient to keep changing the number of turns of wire on the coil, so the circuits are generally arranged in such a way that for a particular waveband—say the long waveband—the inductance is kept constant and the capacity of a variable condenser connected across it is varied to effect the necessary changes in the tuning circuit. To make the operation of the receiver as simple as possible it is usual to choose a value of condenser and inductance such that a complete waveband can be tuned by altering the condenser from maximum capacity to minimum capacity. When it is desired to make a larger change in the wavelengths to which the set will respond, the value of the inductance is changed—by switching in another coil, by the operation of the "wave-change" switch. This enables the same condenser to vary the circuit characteristics over yet another range, the wave-change switch usually providing "long" and "medium" wave range. The tuning condenser is operated by turning the tuning knob on the front of the receiver, the precise wavelength, or frequency, to which the set is tuned being indicated on a dial or other indicator suitably geared to the driving spindle of the variable condenser. Some broadcast receivers are equipped with push-buttons for tuning, and these buttons are either arranged to switch in and out different circuits, each tuned to a specific wavelength, or to operate an electric motor geared to the tuning condenser so that the latter is driven round to the required position and then stopped until a different button is pressed.

Coils and Condensers.—A very desirable, in fact almost essential, feature of a modern broadcast receiver is high selectivity. This means that it must be able to receive the desired station adequately, but without any overlapping and interference from others. It should be apparent from foregoing sections that if this result is to be achieved, the receiver must respond not to one precise frequency only, but rather to a small band of frequencies on either side of the carrier frequency. This is because the modulation of the carrier by the low-frequency programme impulses causes the radiated energy to be spread over a limited band of frequencies known as the "sidebands." In order that the quality of the received programme shall not be impaired, it is necessary that the receiver shall respond to these sidebands as well as the carrier. A selective receiver tuned to a given point will therefore respond to the desired carrier wave and its sidebands, but not to frequencies outside this range.

One important factor in securing a high degree of selectivity is the efficiency of the tuning coils, and much care and ingenuity has been devoted to the design of modern coils in order to reduce all the avoidable losses to an absolute minimum. Almost equally important is the actual arrangement of the circuits themselves in the receiver. The use of several tuned circuits operating together is a potent influence in providing the selectivity necessary under modern conditions, when large numbers of transmitting stations are operating simultaneously on closely adjacent frequencies.

As described earlier, such circuits are generally tuned by varying the capacity of a condenser connected across a coil. The variable condensers usually consist of two sets of interleaving metal plates, one fixed and one movable, insulated from

each other by an air space or other insulator. The amount of capacity in circuit is determined by the degree of interleave of the plates, the moving set being controlled by the tuning knob. When several circuits are required to be tuned simultaneously the condensers in each circuit are "ganged" together by mounting them in one rigid assembly holding the fixed plates, and providing a common driving spindle for all the moving plates The movement of the one tuning knob thus varies all the condensers at once, and so all the circuits are tuned together in one operation.

Detectors.—Having made provision to tune the receiver to the incoming waves, the next step is to incorporate within it some means of detecting the intelligence carried by them. This is necessary, because the incoming waves as received, although modulated by the programme, are still at frequencies far too great to be audible to the human ear, even if the loudspeaker could reproduce them. In some way therefore the low-frequency programme impulses must be sorted out from the carrier, and the latter removed. This is the function of the detector. What it does is to produce a low-frequency current in the receiver, a current which varies in sympathy with the *amplitude* of the waves being received. It does this in the way described below, where the detector is assumed to be a crystal.

Reference to Fig. 2 (*c*) will show that the low-frequency programme currents caused the variations in the amplitude of the carrier wave. The *rate* at which the amplitude of the carrier is changed therefore is the *frequency* of the programme current at any instant, and the *amount* by which the amplitude is changed is the strength or loudness of the programme. The detector, whether it be a crystal or a small metal rectifier, acts as a one-way device, and so when the high-frequency oscillations produced in the tuning circuit by the modulated carrier are applied to it, current passes freely in one direction, but not in the other. The result is that half of the high-frequency oscillations are stopped, and a series of pulses of high frequency are left, all acting in one direction. The rate of change of amplitude of these pulses is the same as that of the currents which modulated the carrier wave at the transmitter. The diagram Fig. 4 shows the pulses in

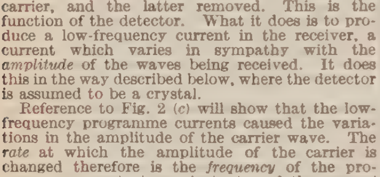

FIG. 4.—SHOWING DETECTION PROCESS.

full lines, and the varying mean current which results from them as a dashed line. Now if a pair of headphones is connected across the detector the individual pulses will be of such a high frequency that they will not operate the diaphragms in the headphones, but the mean current indicated by the dashed line is changing much more slowly, and to this slower change the diaphragms will respond. The mean current is, in fact, varying at low frequency, and is the modulation imparted to the carrier wave by the original programme sounds (compare Fig. 2 (*b*) with the dashed line of Fig. 4), and so the telephone diaphragms, as they respond to its variations, faithfully reproduce the sounds which caused the electrical impulses in the studio microphone.

In a receiver designed for the reception of frequency-modulated waves a frequency discriminator has to be employed, in which the frequency variations are made to cause amplitude variations at the output end, in accordance with the original programme impulses. The wave is then applied to a detector, operating in the ordinary way.

The Diode Valve Detector.—Fleming's original thermionic valve had only two electrodes, and although the addition of more electrodes has increased its usefulness, the original two-electrode type or "diode," as it is called, is still used to-day, being one of the most popular modern detectors. The diode valve consists of the familiar highly evacuated glass envelope containing a fine wire filament and a metal plate called the "anode." If an electric current is passed through the filament it becomes heated and gives off electrons. When the anode of such a valve is positively charged it will attract the negatively charged electrons, which will flow through the valve to the anode and thence through the external circuit, thus producing an electric current. If, however, the anode is negatively charged it ceases to attract the negatively charged electrons emitted by the filament, and the current stops flowing. From this it will be clear that, if the high-frequency voltages set up in the receiver circuits by the radio waves are applied to the anode of a diode valve, current will flow through the valve during each positive half-cycle, while during each negative half-cycle the current will stop. Such a valve, therefore, behaves in a manner identical to the crystal detector already described, suppressing every other half cycle of the high-frequency currents and allowing the remainder—all flowing in one direction—to pass. The resulting uni-directional current impulses produce a "mean valve current" varying at low frequency in the same way as that described for the crystal, and this low-frequency current can be used to actuate the diaphragms of the headphones.

The Triode Valve.—This valve, as its name suggests, is one which contains three electrodes, and was developed by Lee de Forest from Fleming's original diode.

It has a filament and an anode like the diode, but in addition it is fitted with a "grid." This grid is usually in the form of a fine wire mesh placed between the filament and the anode. Normally the electrons leaving the filament can pass through this grid without interruption, and reach the positively charged anode. If, however, the grid has a negative potential applied to it, it will restrict or even stop the flow of electrons to the anode, depending on the strength of the negative potential This important property of a triode can be used to *amplify* weak signals so as to render them strong enough to be useful. If this amplification—the principle of which will be described later—is used before the detector stage it is called high-frequency or radio-frequency amplification, and if used after the detector stage it is called low-frequency amplification.

Both types of amplification are frequently employed to increase the "sensitivity" of a modern radio receiver. The currents flowing in the first receiving circuits are very weak, as they are only those set up by the incoming waves. If the ends of these circuits are connected between the grid and filament of a triode valve the oscillating voltages set up in them by the incoming waves will make the grid alternatively positive and negative. Now if the grid is positive it attracts electrons; if negative it repels them, thus the anode current, or current passing *through* the valve, is caused to rise and fall in sympathy with the incoming signals. These incoming signal voltages are thus enabled to control the much greater power flowing between anode and filaments, which is derived from local batteries or from the electric mains.

Fig. 5 explains this action more clearly. The sloping curve on the left is a typical valve characteristic, and consists of a graph showing the relationship between anode current and grid voltage.

Let us suppose that the normal grid bias applied to the valve whose characteristic is shown in Fig. 5 is $-1{\cdot}5$ volts. It will be seen that with this amount of bias the anode current will remain steady at a value of about 3·5 milliamps., corresponding to point *A* on the characteristic curve. Now the currents set up in the receiver circuits by the passing radio waves are very much less than this. So if the voltage produced by them is applied to the grid, and, for example, varies the grid potential from zero to 3 volts negative, as indicated by the curve below the base line, the anode current will be varied between point *B* and point *C* on the curve. Thus we have a varying current many times stronger than the original, yet, as will be seen from the curve on the right, varying exactly in sympathy with the original.

If a coil is connected in the anode circuit the rising and falling current passing through it produces a rising and falling magnetic field, which, in turn, sets up an oscillating voltage across the coil. Since the changes of anode current are greater than the original changes set up by the radio waves in the first circuit, the voltages appearing across the anode coil will be correspondingly greater, and thus the original signals have reproduced themselves—via the valve—in a considerably amplified form.

A similar type of valve and circuit arrangement may be used for amplifying the low-frequency voltages obtained after detection, thus strengthening them to a power level sufficient to operate a loudspeaker.

The triode can also be used as a detector if a suitable circuit arrangement is employed. One method—known as the "anode bend" method—is to arrange for the grid-bias voltage to restrict the anode current to the point where the curve bends sharply—indicated by point *X* in Fig. 5. When biased to this point, only grid voltages swinging in a positive direction are able to increase the anode current, negative swings having

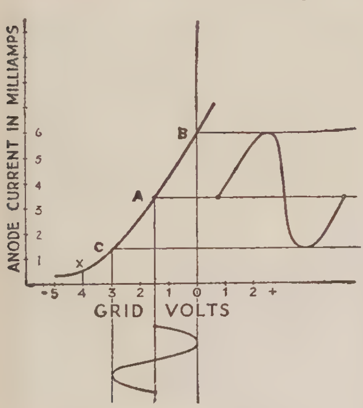

FIG. 5.—SHOWING RELATION BETWEEN GRID VOLTS AND ANODE CURRENT.

no effect upon it. In this way the alternate negative half-waves are suppressed, and the circuit behaves in much the same manner as that of the diode described earlier and illustrated in Fig. 4. Yet another method is to insert a fixed condenser in the grid lead, and a resistance—known as the grid leak—between grid and filament.

Multi-Electrode Valves.—So far we have dealt only with the simpler types of valve—the diode and the triode—but nowadays there are many more complicated types. These have been evolved by the introduction of additional electrodes into the earlier valves in order to improve their amplifying properties for both high and low frequencies, and for various other purposes.

One of the deficiencies of the triode valve is that when used as a high-frequency amplifier there is a limit to the amount of amplification that can be attained owing to the liability of energy being fed back from the anode to the grid—as it were through a capacity—thus causing the arrangement to become unstable. This tendency can be overcome by interposing an extra grid between the anode and the ordinary control grid, and valves of this type—known as the "screen-grid"—are often employed for high-frequency amplification. The extra grid, which is kept at a steady potential somewhat lower than that of the anode, screens the latter from the control grid, prevents the feed-back of energy from the anode to the control grid, and so permits greater amplification to be achieved without instability.

For low-frequency amplifiers the "pentode" valve, having five electrodes, is commonly used. This valve is capable of handling a large amount of power and has a high amplification factor: it is therefore particularly suitable as a final amplifier in a receiver, where it can be utilised to provide a relatively large amount of power for the loudspeaker. Five electrode valves of a different type are also employed for high-frequency amplification.

It is also common practice to perform the functions of more than one valve within a single glass bulb—*i.e.*, one valve envelope may, for example, contain assemblies to amplify high-frequency oscillations, generate local oscillations, and detect. The diode detector is often included within the bulb of another valve; sometimes there are two diodes—one to act as a detector and the other for automatic volume control—as well as a triode assembly, all within the one bulb. In superheterodyne receivers it is necessary to generate local oscillations in the receiver itself and to mix these with those set up by the incoming signals, and for this purpose several different valve types having various arrangements of electrodes are in use.

Semi-Conductors.—Many of the functions of thermionic valves are nowadays being performed by various types of semi-conductors, the increasing use of which promises to effect big changes in the design of radio receivers and other radio equipment. It is interesting to note that the crystal detector, which was in use for many years before the advent of the valve detector and whose function has already been briefly described, was itself a particular example of the use of a semi-conducting device. During recent years the properties of certain crystalline materials have been more closely investigated, and as a result crystal diodes have been produced which possess several advantages over valves. But, more important, it was soon found that crystals, if built up or arranged in a suitable manner, could provide amplification, and thus could be used as amplifiers or as oscillators, in many instances in the place of valves. The crystal material used—principally germanium into which an impurity has been introduced, or sometimes silicon similarly treated—performs its function in a way which is not easily explained, but the following simplified description may serve as an indication of the uses to which semi-conductors are being put in modern radio-equipment.

Crystal Diodes.—Crystal diodes are of two main types: (*a*) junction diodes, and (*b*) point-contact diodes.

Junction diodes consist, typically, of a germanium crystal into part of which indium has been introduced at a high temperature. The part consisting of the pure germanium contains, essentially, only negative electrons and is known as "*n*-type" material, whereas the part which has been adulterated with indium possesses positive electric properties, containing only positive "holes" as they are called, and is known as "*p*-type" material. The transition from the *n*-type to the *p*-type material is called the junction. If a voltage is applied across the junction in such a direction as to cause negative electrons to flow over the junction from the *n*-type to the *p*-type material and positive holes from the *p*-type to the *n*-type, then a large current will flow. If, however, the voltage is applied in the reverse direction, then no current (or very little) can flow, because there are no negative electrons in the *p*-type material to flow to the *n*-type, and no positive holes in the *n*-type to flow to the *p*-type material. The crystal, therefore, behaves as a one-way device and acts in the manner described in the section "Detectors," and in a manner similar to that of a valve-diode, already described. It is therefore suitable for use as a detector in radio circuits, *i.e.*, for separating the low-frequency programme currents from the high-frequency oscillations of the radio wave, and for other uses to which a valve diode may be put.

Point-contact diodes consist of a pointed wire in contact with a crystal, and the old crystal detector, already mentioned, was, in fact, just such a device. The crystal may be of germanium

(n-type) or silicon (p-type) and the wire "whisker" of tungsten or platinum, in each case the whisker being of the opposite electrical characteristic to that of the crystal. In effect, a junction is formed in the crystal just below the point of contact of the whisker, and the arrangement, therefore, behaves as a one-way device in a similar manner to that of the junction diode.

Transistors.—Crystal arrangements designed to act as amplifiers are known as "transistors" and these again are of the two main types: (*a*) junction transistors, and (*b*) point-contact transistors.

Junction transistors consist, typically, of crystals in which there are two zones of p-material separated by a thin section of n-material. (The reverse arrangement may also be used.) Imagine such a crystal with p-material on its left-hand side, n-material in the centre, and p-material on its right-hand side. The left-hand side is known as the *emitter*, the centre as the *base*, and the right-hand side as the *collector*. The "input" circuit is connected between emitter and base in such a direction that large current can flow across the junction, whereas the "output" circuit is connected between collector and base so that only a small current can flow across its junction with the base. However, the large currents flowing in the base from the input circuits are common to the collector circuit as well, and they increase the previously small collector currents. These increases in the collector currents are of great account, for, owing to the direction in which the output circuit is connected across the collector and base (*i.e.*, its greater impedance) they can give rise to much greater voltage variations in that circuit than could the same current variations in the input circuit. Thus amplification has been achieved and the transistor can be used to perform the functions of a valve amplifier or of an oscillator, though to do so it must be connected in circuit in a somewhat different way from that in which the valve is connected.

Point-contact transistors consist of crystals, usually of germanium, with two wire whiskers touching the surface only a few thousandths of an inch apart. The action of this device is similar to that described above the whiskers forming the emitter and collector respectively, and the crystal the base. If the emitter and collector are sufficiently close, currents flowing in the crystal under the former can cause current variations under the collector, and so vary the currents in the output circuit. The latter can be considerably greater than those in the emitter circuit, and this, together with the different impedance in the two circuits, gives rise to the amplifying effect.

It will be evident that crystal diodes and transistors possess several advantages over valves which are designed for similar work, since there is no need for evacuated glass bulbs nor for a heated emitter to give off electrons. This leads to much greater compactness and economy as well as to a much longer life. However, there are certain limitations to their use, and they are not yet suitable as substitutes for valves in all cases. But their development and improvement is proceeding at such a rate that their uses are continually increasing, and it appears that this trend will continue into the future.

The Super-Heterodyne Receiver.— Most modern broadcast receivers are of the "super-heterodyne" type, in which the "heterodyne" principle of reception is employed. In this system local high-frequency oscillations are generated within the receiver, but of a slightly different frequency from those being received. The two sets of oscillations are allowed to "beat" together, and the result is that, after detection, a third set of oscillations of yet another frequency is produced.

The advantages of the super-heterodyne receiver are that the necessity for tuning all the circuits of the amplifiers to the wavelengths or frequency of the incoming wave is avoided, and most of the amplification required can be performed at one fixed high frequency, no matter what wavelength is being received. This permits the amplification to be carried out in a particularly efficient way, since the circuits can be designed to work at maximum efficiency when only a single frequency has to be handled; furthermore, the system greatly facilitates interference-free reception.

The super-heterodyne receiver uses an oscillator so arranged as to be always mistuned to the frequency of the incoming signals by a certain fixed amount, so that "beats" at, for example, 465 kilocycles per second are produced, irrespective of the frequency being received. These beats are detected and passed to the anode of a valve, where oscillations at 465 kilocycles per second are established. This frequency is termed the "intermediate frequency," and the circuits of the succeeding amplifying valves remain constantly tuned to this one frequency. If a broadcast programme is being received, then the amplitude of the intermediate frequency oscillations varies at audio-frequency, and a second detector is required to sort out the audio-frequencies of the programme from the intermediate frequency, so that they may be fed to the loudspeaker.

Automatic Volume Control.—As has already been explained, the anode current flowing through a valve may be limited by the application of a steady negative voltage to its grid. This is called grid "bias," and it may be derived from a battery or from the voltage developed across a resistance in the circuit. In modern receivers this characteristic is made use of to counteract "fading," *i.e.*, the rise and fall in the strength of the incoming waves due to variations taking place during their journey from the transmitter to the receiver. A diode valve is incorporated in the circuits following the intermediate-frequency amplifier and supplied with voltages at the intermediate frequency. These are then detected and fed back to the control grids of the pre-detector amplifiers. Thus, when the strength of the incoming signals rises above normal a negative voltage is applied to the amplifying valve control-grids, and so their amplification is reduced. Conversely, when the incoming signal strength drops below normal, less negative voltage is fed back from the diode to the amplifier-valve grids, their amplification is increased, and more voltage is delivered to the second detector. In this way most types of fading can be overcome, or at least considerably reduced, and the input to the low-frequency end of the receiver maintained at an approximately constant level.

Stereophonic Broadcasting.—A person having normal hearing is able to determine the direction from which a sound reaches him by virtue of the fact that he has two ears, and, therefore, the sound will reach one of them a fraction of a second before it reaches the other. This difference in arrival time allows the brain to calculate direction.

It will, therefore, be apparent that if the same person listens to, say, an orchestral concert in a large hall he will be able to determine—even with his eyes shut—the approximate position of a particular instrument with respect to the rest of the orchestra. If, however, he listens at home to a broadcast of the same concert, then, due to the fact that he hears the music after it has been picked up by a single microphone located at one point and radiated over a single-channel transmission system, he will be unable to allocate a definite position to any instrument.

The aim of stereophonic broadcasting, or sound reproduction, therefore, is to restore the listener's ability to locate the position in space of the various sources of sound and to follow movement.

To do this it is necessary to use two microphones in the studio—to simulate the two human ears—and to transmit their outputs, through two similar, but separate, chains of equipment, to two radio receivers and their two loudspeakers, which must be placed some distance apart, in the listener's home. The idea of stereophonic broadcasting is not new; as long ago as 1926 the B.B.C. carried out experiments using two medium-wave transmitters. The advent of stereophonic records, both discs and magnetic tapes has, however, re-awakened interest in the subject, and

during 1958 and 1959 the B.B.C. carried out a series of experimental broadcasts, in which the "left-hand" channel was carried by the medium-wave and v.h.f. Third programme transmitters and the "right-hand" channel by the television sound transmitters.

The system outlined above, which was used for the experimental broadcasts, suffers from a number of disadvantages which would render it unsuitable for a regular service. For example, at least two transmitting stations must be used to radiate the signals, which is very costly and wasteful of transmitter facilities, whilst it is impossible for those listening to only one of the transmitted channels to obtain properly balanced reproduction. These difficulties, to mention only two, have prompted broadcasting authorities all over the world to re-examine the problem. The B.B.C. is therefore investigating the various possible methods of radiating stereophonic programmes from a single v.h.f. transmitter. The European Broadcasting Union has set up a committee to examine the results of various tests and to endeavour to formulate a common specification for stereophonic broadcasts in the European area. In the United States a committee is also examining numerous different systems and suggestions. It will be apparent from the foregoing that the matter is being very fully investigated to ensure, as far as possible, that whatever system may be adopted it shall give the most satisfactory results whether received stereophonically or not. If any such system is introduced in the future it will necessitate special receiver circuits capable of separating the left- and right-hand channel programme information and followed by twin amplifier and loudspeaker equipment similar to that at present used for the reproduction of stereophonic recordings.

Power Supplies.—Portable radio receivers and certain sets intended for use, for example, in ship's lifeboats or in remote country districts, derive their power from batteries, but the vast majority of modern receivers are fed from the electricity-supply mains. There are two kinds alternating current (A.C.) and direct current (D.C.). Alternating current mains supply is nowadays almost universal, and in the A.C. mains-operated receiver power is supplied to a transformer which changes the voltage to values appropriate for the "high-tension" and "low-tension" supplies for the valves. In the case of the "high-tension" supply the power has to be converted to direct current (D.C.), and this is done by a rectifier, which may be a metal-rectifier, a mercury-vapour rectifier, or a double-diode valve. Like the detector any of these rectifiers produces a series of unidirectional pulses of current. These pulses require "smoothing," and this is carried out by means of condensers and a choke coil, the final smoothed D.C. supply being fed at a suitable voltage to the anodes of the receiver valves.

Receivers working from D.C. mains cannot be fitted with transformers, and their circuits have therefore to be designed to operate at voltages slightly below those commonly found in D.C. mains supplies. Resistances are used to provide voltages below those of the mains, and smoothing equipment is incorporated to remove any "ripple" present in the supply, as this, unless smoothed out, would produce unwanted noises in the programme heard from the loudspeaker.

The valves may be heated directly or indirectly, and the filaments of the directly heated type or, the heaters of the indirectly heated type, are supplied from low-voltage windings provided for the purpose on the mains transformer in the case of A.C. operated sets. In the case of sets operated from D.C. mains they are supplied through high resistances which "drop" the mains voltage to the appropriate value.

The development of semi-conducting devices as detectors and amplifiers has led to their introduction in place of valves in an increasing variety of miniature portable equipment. Since the power requirements of the crystal diodes and transistors used in this apparatus are much less than those of comparable valves they are operated from small dry batteries of similar size to those used in pocket flash lamps.

TELEVISION.

Historical.—So important is the sense of sight that men have, from very early times, been constantly trying to increase its range and to enlarge its power. It is not surprising, therefore, that many of the scientific discoveries that have gone to make television possible took place before radio itself had become a practical proposition. One of the most significant of these was the result of a pure accident, which led to the discovery by Willoughby Smith in 1873 that the electrical properties of selenium vary according to the amount of light to which it is exposed. This discovery pointed to the possibility of converting light waves into electrical impulses.

Here certainly was the first requirement for the transmission of sight by radio or by wire, but it was evidently by no means enough, for it did not show how all the infinite variations of light and shade in a scene were to be transmitted to a distance and yet presented to the viewer's eye simultaneously. It was evident that the scene would have to be broken down into a number of small elements, each of which could be transmitted separately and then reassembled at the receiving point. The thing must be done so rapidly as to deceive the eye into thinking that it sees all the elements at once, and furthermore, consecutive pictures must be built up so rapidly as to give the eye the impression that it sees a continuously moving scene.

A means of doing this was provided by Nipkow in 1884, when he invented his famous scanning disc, and later Weiller invented the mirror drum for the same purpose. Such mechanical devices as these held the field for many years, and in 1923 Baird in this country and Jenkins in America were both using them for the experiments which, in 1925, led to the successful transmission of shadows and simple outlines. It was not until 1926, however, that the first practical demonstration of television, as we understand it, took place. In London, on 27th January of that year, Baird transmitted by radio moving pictures of living human faces over a short distance.

In 1927 transmission of a picture by wire over a distance of 250 miles took place in America, and the demonstration was repeated by radio shortly afterwards.

In 1929 the B.B.C. gave facilities to Baird Television Ltd. for experimental television transmissions. The programmes, which originated in Baird's studio in Long Acre, were radiated by the B.B.C.'s Oxford Street (2LO) station on a wavelength of 365 metres. These transmissions used 30 scanning lines to the picture, and 12½ pictures per second were transmitted. The Oxford Street station radiated vision only, but in 1930 this low-definition television service was transferred to the B.B.C.'s new London Regional transmitting station at Brookmans Park, and sound was added to the programmes. The 30-line transmissions were of sufficient technical interest for the B.B.C. to equip one of the studios in Broadcasting House, London, with Baird apparatus, and this was brought into operation in 1932.

At this time much thought and energy was being expended upon the problem of improving the "definition" of the television pictures, and it was becoming apparent that a satisfactory standard could not be reached using mechanical scanning methods. Attention was returned to an idea which had been put forward by A. A. Campbell Swinton as long ago as 1908, when he had suggested a television system using cathode-ray tubes at both the transmitter and receiver. He had expanded this idea in his presidential address to the Röntgen Society in 1911, when he envisaged a special type of cathode-ray tube at the transmitter—the forerunner of the television "camera" of to-day. At the same time he described in detail arrangements for moving the beams of the transmitting and receiving tubes exactly in synchronism. The great advantage of this idea was that by using an agent like the cathode-ray, which possesses practically no weight or inertia, and is, therefore, capable of being swung about with tremendous speed and accuracy, the great difficulty with the mechanical systems of securing the extremely accurate yet rapid motion of the scanner, disappeared.

By 1934 "cameras" on these principles had

been developed both by the Marconi-E.M.I. Co. in this country and by Zworykin in America, and it seemed possible that a television service with markedly improved definition might be practicable. In May 1934 the Postmaster-General appointed a committee under the chairmanship of Lord Selsdon to report on the relative merits of the various systems then being developed

On the recommendations of this committee the B.B.C. was entrusted with the task of erecting a television transmitting station at Alexandra Palace, London, and Baird Television Ltd. and the Marconi-E.M.I. Television Co. Ltd. were invited to tender for the supply of apparatus for their respective systems. These two systems were operated alternately, the Baird system on 240 lines, 25 pictures per second with sequential scanning; the Marconi-E.M.I. system on 405 lines 25 pictures per second with interlaced scanning, giving 50 frames per second. The Radio Exhibition at Olympia in August 1936 was the occasion of the first public transmissions by the two systems from Alexandra Palace on an experimental basis, and the station recommenced transmissions with a series of trial programmes in October, these lasting for two hours daily.

The Alexandra Palace Station was formally opened by the Postmaster-General on November 2, 1936, and this marked the start of the world's first public high-definition television service. Programmes were radiated for two hours each day, the two alternative systems being used during alternate weeks. On February 5, 1937, the Postmaster-General announced that the Television Advisory Committee, as a result of the experience gained from these transmissions, recommended the adoption of a single set of standards—those of the Marconi-E.M.I. Co. Accordingly, from February 6, 1937, this became the standard system for British Television, and the service from Alexandra Palace continued until the outbreak of war, when the station closed down. Alexandra Palace reopened to provide a television service for the London area on June 7, 1946, using the pre-war standards.

Since that date the B.B.C. has built and brought into service twenty-three new high-, medium-, and low-power television transmitting stations, and by the end of 1959 its television service was available to over 98% of the population of Great Britain. Many other television stations are, of course, operating in America, Europe, and elsewhere.

The London Television Transmitting Station was moved to Crystal Palace, Sydenham, in March 1956, and its power increased. This and other measures, including the provision of satellite or translator stations, such as that at Folkestone, to serve areas in which satisfactory reception is at present difficult or impossible, will increase the coverage of the B.B.C.'s television service still further.

A translator, like the one at Folkestone, which came into service in July 1958, converts the sound and vision transmission frequencies from one channel to another without demodulation to audio and video frequencies as would be necessary if a conventional receiver and transmitter relay installation were used. This simplification increases the reliability of the equipment and enables it to be arranged for automatic operation without attendant staff. As the equipment is small it can be housed in weather- and insect-proof steel cabinets of existing design, thus dispensing with the need for station buildings. It is so designed that it only requires the connection of a local electricity main to supply all its power requirements.

A translator needs to be situated on high ground where good reception from an existing station is possible and whence its transmissions can be radiated over line-of-sight paths in the area to be served. Such siting allows a very low-power output to be used, and thus does not add to the already serious co-channel interference problem.

The B.B.C. is developing similar translator transmitters to extend the v.h.f. sound broadcasting service to small areas at present prevented by intervening high ground from obtaining direct reception from the main stations.

In June 1959 the Postmaster-General approved in principle the construction by the B.B.C. of twenty-four additional low-power stations within the next three years to extend the coverage of its television and v.h.f. sound services. Most of these stations will be translators.

The B.B.C. has in existence plans for the provision of alternative programmes and for the development of a system of colour television. The Television Advisory Committee has recommended, however, that any colour television system which may be used in the future should be so arranged that its transmissions would provide black-and-white pictures on receivers not designed for colour. The B.B.C. has done much preparatory work on colour television, starting as long ago as 1946. Close liaison is maintained with the Television Advisory Committee, the G.P.O., and the Radio Industry. Since 1955 the B.B.C.'s Research and Designs Departments have collaborated in a series of experimental colour-television transmissions from Alexandra Palace and latterly from Crystal Palace. For use in these experiments the B.B.C. installed a colour-television studio at Alexandra Palace provided with two colour cameras, 16-mm. and 35-mm. colour telecine machines, and all the necessary control-room equipment.

The colour system used in these experiments is a modified form of the N.T.S.C. (National Television System Committee) system used in the U.S.A. This system has been adapted by the B.B.C. to suit the British 405-line standards and can be radiated by a normal transmitter as used for the black-and-white service. The transmissions can also be received in black-and-white by a normal television receiver tuned to the appropriate channel, thus complying with the recommendation of the Television Advisory Committee. Colour television using this system has been successfully demonstrated by the B.B.C.'s Engineering Division to the members of both Houses of Parliament, to the Institution of Electrical Engineers, and other bodies, while colour test transmissions are frequently radiated from the Crystal Palace station outside normal programme hours.

In addition to the television programmes provided by the B.B.C. separate programmes have, since September 22, 1955, been radiated by the Independent Television Authority starting with its station near Croydon, Surrey. The I.T.A. had, in the autumn of 1959, ten transmitting stations covering approximately 90% of the population of Great Britain, and additional stations are planned to increase this figure.

The General Principles.—There are certain fundamental differences between the broadcasting of sound and television, and these differences are mainly concerned with the senses by which the broadcasts are perceived. The ear, with which sound broadcasting is concerned, will respond to a single note, but if a chord is struck it does not differentiate between each individual note, but presents to the brain a composite sound made up of all the notes in the chord. In all cases where there is a combination of sounds, such, for example, as in speech or music, it is a complex wave combining all the sounds together which excites the ear-drum and is passed to the brain.

The sense of sight, however, is completely different in its method of operation, and to understand the problems of television it is necessary to consider the action of the human eye. Basically the eye consists of a lens which projects an image of the scene before it upon the retina, a light-sensitive screen at the back of the eye. The retina is made up of several millions of tiny light-sensitive elements, each quite separate and distinct from its neighbours, and each separately connected to the brain by an individual fibre in the optic nerve. Thus the eye is a very complex organ, and it is able to pick out numbers of tiny details from a scene and convey each detail separately and simultaneously to the brain. It does not send a blend of different points of light and shade in the same way that the ear sends a blend of different sounds; if it did the brain would receive a completely unintelligible blur. From this it will be seen that a television system which transmitted a mixture of detail would be useless; it must transmit all the details in a scene separately, yet almost simultaneously, and re-assemble them at such a speed that the eye cannot observe the

building-up process. The photo-electric cell reacts to light in a manner similar to the light-sensitive elements of the eye, and would therefore reproduce picture details as electrical impulses, but in order to produce a picture having good definition it is necessary to transmit nearly a quarter of a million separate details. As it is obviously out of the question to use such a large number of cells, each requiring a separate radio transmitter and receiver, to convey the information, some artifice is necessary to make television practicable. The one used is known as "scanning." This process, which is carried out in the television camera, consists of dissecting the scene into a large number of small pieces, rather like the dots visible in a newspaper reproduction of a photograph. Each one is then transmitted separately, and they are re-assembled at the receiver so rapidly that the eye is tricked into believing that it sees the whole picture at the same time.

In the scanning process the picture is divided up into a large number of horizontal lines, each line consisting of a number of the small pieces just mentioned, and the detail in each line is detected by the scanning beam and faithfully reproduced by a similar beam at the receiver. The scanning beam sweeps along a particular line and then flies back to the beginning of the next line to be scanned, much as the eye, in reading, sweeps along a line of print conveying the sense of each separate word to the brain. Just as the eye pauses at the end of a page or column and starts again at the top of the next one, so the scanning beam pauses at the end of each complete "field" of the picture and returns to the starting-point for the next scan. The scanner also transmits "synchronising pulses," which tell the receiver when to start each new line and each new "field" or picture. As the eye normally takes about $\frac{1}{16}$ of a second to register a scene, any happening taking less than $\frac{1}{16}$ of a second is not properly observed. Thus, if successive pictures are built up with sufficient rapidity the fact that they *are* separate pictures is not conveyed to the brain. The ordinary cinematograph relies on this principle of "persistence of vision" to create the impression of continuous movement.

The television standards used in Great Britain are based on the transmission of twenty-five complete pictures every second, each picture being composed of 405 horizontal lines. The twenty-five pictures per second are not in themselves sufficient to avoid "flicker," and this is overcome by using "interlaced" scanning. In this system the scanning beam first passes over all the odd-numbered lines from top to bottom of the picture, and then returns to the top and scans all the even numbered lines. The two "fields" thus produced mesh together to form the complete picture, but as the fields are transmitted at the rate of fifty per second, there is no noticeable flicker.

Let us now consider some of the apparatus which makes television possible.

The Television Camera.—Although there are several different types of television camera in use at the present time, they all make use of a lens system to produce an image of the scene before the camera upon a photo-electric plate. Probably the simplest one to understand is the original "Emitron" camera, a simplified diagram of which is shown in Fig. 6. It will be seen to consist of a highly evacuated glass tube with a large bulb at one end. This bulb contains the mosaic screen (*a*) upon which is focused, by means of the lens (*b*), an image of the scene to be, transmitted, the light rays passing through the "window" in the bulb. The mosaic screen consists of a sheet of insulating material backed by a metal plate. On the front of the screen is the mosaic itself, which is made up of several thousands of minute light-sensitive elements—each virtually a tiny photo-electric cell—every one of which is electrically separated from those surrounding it. Each of these little cells takes up an electric charge proportional to the amount of light falling upon it, and thus the mosaic as a whole acquires an "electrical picture" of the scene. In the tube below the bulb is situated the "electron gun" (*c*), which aims a finely focused beam of electrons at the mosaic. The deflector coils (*d*), near the neck of the tube, cause the beam of electrons to move across the mosaic in a series of horizontal lines, first the odd-numbered lines then the even-numbered lines, as mentioned earlier. As the electron beam passes over each of the "cells" of the mosaic, the cell is discharged and, as a result of this, a series of minute electrical impulses is induced into the

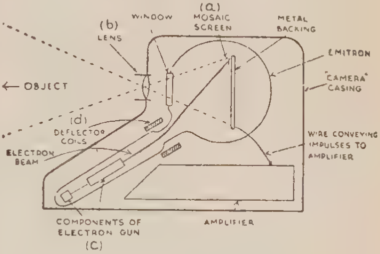

FIG. 6.—TELEVISION CAMERA.

metal back plate of the screen, each impulse being proportional to the amount of light falling upon the cell from which it emanated. These impulses are extracted from the tube, along the wire which passes out of it. In this way the picture is taken from the camera spot by spot and line by line as a series of electrical impulses. These impulses are amplified and have added to them the "line-synchronising" and "frame-synchronising" pulses, and are finally used to modulate the carrier wave of the vision transmitter, which carries them through space to the receiver. The emitron high-velocity type of camera tube described above has been superseded by later types of tube including the "C.P.S. (cathode potential stabilized) emitron," the "image orthicon," and the "vidicon." These tubes have various advantages over the earlier type, for example, the C.P.S. emitron produces a definite black-level output signal; being cylindrical, it is more conveniently mounted in a camera; it does not produce spurious signals, and its sensitivity and resolution are much better. Its chief disadvantage is that blurring can occur on moving images unless careful control of the operating conditions is exercised.

The image orthicon camera tube has a very high sensitivity, it can resolve images at very low lighting levels, at which other camera tubes would be useless, and this high sensitivity makes it particularly valuable for outside broadcast work. It produces a definite black-level output and gives good reproduction of rapidly moving high-lights. The chief disadvantage of the image orthicon tube is that it is necessary to maintain the temperature of the mosaic or "target" within narrow limits and to obtain normal operating temperature it must be switched on at least half an hour before it is required.

All the camera tubes described above are of the "photo-emissive" type, that is to say each of the minute photoelectric cells forming the "target" emits electrons in direct proportion to the amount of light falling on it. A different type, the "photo-conductive" or "vidicon" tube, has come into use in recent years and depends for its operation on the fact that the electrical resistance of certain materials changes when they are exposed to light. The change is usually rather slow, and if such materials are used for camera-tube targets the images of rapidly moving objects are smeared.

This type of tube, however, is small and comparatively simple, facts which render it particularly suitable for use in small or lightweight cameras. It has applications in television broadcasting for programmes in which rapid movement is unlikely and is also well suited to many industrial uses or for some telecine equipment where the high-light levels possible reduce smearing. Another valuable feature of the vidicon tube is that it can be used as soon as the electron gun has warmed up.

The Television Studio.—As with sound broadcasting there are several intermediate stages between the camera and the transmitter. In this country the studios operated by the B.B.C. in London and the Provinces contain up to four cameras each, and their outputs are taken to the "vision" mixer panel in the vision control room associated with each studio. In this room the pictures viewed by each camera (and sometimes a picture obtained from a "telecine machine") are displayed on picture monitors in front of the producer. As the programme proceeds he and his assistant select the particular camera or telecine output to be transmitted. They can make an instantaneous change from one picture to another, fade one out and another in, or superimpose one upon another according to the programme requirements.

Telecine machines are devices which allow cinematograph films to be included in television programmes either as effects inserts, *e.g.*, a street scene with moving vehicles to establish a particular location in a play, or full-length documentary or feature films, much as a gramophone pick-up allows records to be used in sound broadcasting.

Early telecine machines operated on the basic principle of pointing a standard television camera at the lens system of a special cinematograph projector, and although some machines still make use of this arrangement for certain purposes, the method had numerous disadvantages, and more modern machines have been developed using different systems for televising normal types of cinematograph film. A very brief description of one sort of telecine machine must suffice. In this the film is run through smoothly and continuously at a speed corresponding to 25 film frames per second. The picture in the "gate" of the equipment is "illuminated" by passing it in front of a cathode-ray tube displaying a "plain raster" or blank television line structure. This raster is, however, compressed to half its vertical height and arranged, through a system of dual lenses and a shutter, so that as the film frame moves downwards through the gate it is scanned by, say, the odd line scan of the television raster. Due to the fact that the film is moving in one direction and the scanning beam in the other, the beam will traverse the entire film frame whilst the latter has moved only half-way through the gate. At this moment the shutter opens to expose the scanning beam—this time the even-line scan—to the lower half of the gate, and cuts off the beam to the upper half. The scanning process is then repeated for the even lines of the picture. The light from the raster passes through the film and falls on a photo-cell. As the light level received by the photo-cell changes in accordance with the light and dark areas in the picture, so the photo-cell produces a changing output which constitutes the vision signal.

In addition, other special effects devices permit sections of a picture produced by one camera to be replaced by pictures produced from a second. This allows, for example, one camera to reproduce, say, a photograph of the Savoy Hotel, whilst another looks at a full-size window of identical design with those in the photograph of the Hotel. By means of a device known as "Inlay" the picture seen by the viewer will be composed of the outputs of the two cameras in such a way that the real window replaces one of the windows in the photograph. Thus an actor can, apparently, open a window in the Savoy Hotel, lean out and wave to a friend, although he is, of course, still in the television studio. Another technique, known as "Overlay," permits a similar subterfuge to be perpetrated, but in this case the shape and position of the suppressed part of the first camera's output is determined by the shape and position of the selected portion of the second picture which is to be "overlaid." The two pictures can be moving ones and, if desired, their scales may be different so that a real dancer may appear only a few inches high and may be made to vanish into a cigarette box or to dance on a man's hand.

The principle involved in both inlay and overlay is that of switching from one camera output to another at a particular instant of time. Obviously the speed of the camera-scanning beam precludes the use of a mechanical switch for this purpose, and an "electronic switch," a device containing some twenty valves, is used instead. This switch is controlled by a device known as a "silhouette generator" which comprises a cathode-ray tube facing upwards and normally displaying a plain raster to a photo-electric cell mounted above it. The light from the raster falling upon the photo-cell causes a small current to flow from it, and this is used to operate the electronic switch to, say, camera 1. If the light is interrupted the photo-cell current ceases and the switch changes over to camera 2. Since the scanning beams of the silhouette generator and the two cameras are all synchronised, they will all, at any given instant, be directed at the same point of the picture area. In the example given above, therefore, if we consider one line of the television picture the scanning beam of camera 1 travels across the image of the photograph of the Savoy Hotel until it reaches the edge of the desired window frame. Simultaneously the beam of camera 2 travels across its target until it arrives at the edge of the image of the real window-frame in the studio. At precisely the same instant the scanning beam of the silhouette generator tube reaches a point at the edge of a black paper mask placed on top of the tube face. As the silhouette generator beam passes under the paper mask the light from its spot is obscured, thus causing the electronic switch to change over to camera 2, which is now scanning the real studio window. At the end of the paper mask the light spot on the silhouette generator reappears, the photo-cell current is restored, and the switch reverts to camera 1, thus reinstating the photograph for the remainder of that line scan.

To facilitate exact registration of the paper mask means are provided whereby, on setting up, the silhouette generator tube can display the output of camera 1 and thus permit the mask to be fitted accurately to the part of the image it is desired to remove.

In the case of the overlay technique the subject is placed in front of a brightly lit white screen and particular attention is given to clothes, make up, etc., to ensure that the signal level emanating from the subject shall be appreciably lower than that from the white screen. The result is that on any line scan there is a sharp drop in the signal level as the subject is reached and a corresponding increase as it is left and the screen reappears. This drop and rise in signal level is used to operate the electronic switch and changeover from camera 1 to camera 2 and back again at the required instant. It will be seen that the subject in front of camera 2 is free to move about within the limits of the particular camera angle in use and will automatically cut an appropriately shaped and moving area from the scene viewed by camera 1, thus giving the impression that the composite scene is being viewed by a single camera. Either or both cameras could be replaced by a telecine machine is required.

Another very useful subterfuge in the television studio is known as "back projection." Adapted from film-studio practice, it makes use of a translucent screen behind the actors and any necessary properties or scenery, on to which can be projected, from behind, a lantern slide or a moving picture as part of the scene. This is particularly useful for creating a realistic background, which can be changed instantaneously or for simulating movement. For example, one scene in a play might take place on a yacht anchored off Cowes. A lantern slide of Cowes as seen from the sea could be projected on the screen, which would be erected behind the physical scenery representing the deck of the yacht. A gentle rocking of the slide would give the impression of the yacht rising and falling on the swell. In a matter of seconds the play may demand the same yacht in Falmouth harbour. A change of slide would meet this requirement.

Simulation of movement is sometimes required, for example the action of a play might take place in a train between Paddington and Plymouth. A dummy compartment erected in the studio would have a screen placed outside its windows and a film taken on an actual journey would be back-projected on to it. The viewer would see the scenery and stations passing by, and so gain the impression of being on a moving train.

For certain items in television production, particularly news and interviews, it is sometimes difficult to get the subject to the studio at the right

time. In the B.B.C. television service these problems have been overcome to some extent by the provision of unattended studios and by remotely controlled cameras. Such a studio in Westminster is frequently used by the B.B.C.'s Parliamentary correspondents.

The outputs from the individual studio control rooms are passed through a central control room which performs a similar function to that of its sound counterpart. In addition, means are provided for adjusting the technical quality of the pictures. From the central control room the vision signals are fed to the distribution network linking the studio centres with the transmitters.

Television Distribution Network.—This is the apparatus employed for conveying the television programme from the studio to the distant transmitters, and in this country the G.P.O. provide and maintain this equipment. Since the frequency range required for picture signals is very much greater than that necessary for sound broadcasting, different and more complex apparatus is required. Cables are used for conveying the picture signals from London to Birmingham, although a radio-link is also available in case of need. The former are of a type known as "co-axial" cables, and are specially designed to carry very high frequency currents. Since the losses are greater at vision than at sound frequencies, repeater stations have to be closer together than would be necessary for sound circuits. Co-axial cables are also used between Birmingham and Manchester and London and Cardiff. The programme for the Kirk o' Shotts station in Scotland is relayed from Manchester by a series of radio links.

In the case of some stations, such as Rowridge in the Isle of Wight, Divis in Northern Ireland, and Norwich, the vision programme from one of the high-power transmitting stations is received by the G.P.O. on specially designed receiving equipment. It is then passed either directly over a short length of cable or over one or more radio links to the transmitting station. Other stations such as North Hessary Tor pick up their vision signals by radio direct from an adjacent B.B.C. television transmitter without the intervention of the G.P.O.

The Television Transmitter.—The principle of the television transmitter is similar to that of transmitters used for sound broadcasting, except for certain special features. In order to convey the extraordinarily large number of impulses which go to make up the vision information, the frequency band required for the radiated energy is much wider than for a sound transmission, and this large band-width of about 5 Mc/s. (5 million cycles per second) can only be provided in the very high frequency bands. The television transmitting stations at present operating in Great Britain occupy the frequency band 41–68 Mc/s. and 174–216 Mc/s., Bands I and III respectively.

As explained earlier, the use of these very high frequencies limits the range of the transmitters and consequently good reception is usually obtained even from the high-power stations only out to a distance of about 50 miles, although satisfactory pictures are often obtained beyond this distance under favourable conditions. The bands mentioned above are divided into channels. Nos. 1–5 in Band I and Nos. 6–13 in Band III. Each of these channels carries, or will eventually carry, a television programme—although not all channels will be receivable in all districts—and in some cases transmitters widely separated geographically may share the same channel. For example, the B.B.C. transmitters at Kirk o' Shotts in Scotland and Rowridge in the Isle of Wight share channel 3, whilst the I.T.A. transmitter in London shares channel 9 with its counterpart in Lancashire.

The Television Receiver.—So that viewers may select the channel or channels appropriate to the districts in which they live, most modern television receivers are fitted with some form of tuning device covering all thirteen channels in Bands I and III. There is, of course, no point in providing continuous tuning as is commonly done in sound receivers. The vision and sound signals from the transmitters are received by a single aerial, but, owing to their being on different frequencies they are separated by the tuned circuits in the receiver, and fed to the vision and sound sections of the receiver respectively, the sound section following normal broadcast-receiver practice. The vision signals are amplified in much the same way as that described for sound broadcasting, and are ultimately applied to the circuits controlling the cathode-ray tube. This consists of an evacuated glass tube containing an electrode which, when heated, emits electrons. The electrons are accelerated and focused into a very thin beam, which can be deflected in vertical and horizontal planes by coils provided for the purpose. Beyond these coils the glass tube is splayed out, and its end is flattened so as to form the viewing screen, the inside of this part being coated with a very thin layer of fluorescent material which glows when bombarded by the electron beam. The brilliance of the glow is proportional to the number and speed of the electrons striking it. The amplified vision signals are caused to vary the strength of this beam, and it is made to move across the screen in horizontal lines one below the other, this movement being controlled by the "line-synchronising pulses," which are added to the vision signal before transmission. It will be seen, therefore, that as the beam moves across a particular line it causes the fluorescent material on the end of the tube to glow more or less brightly according to the strength of signal which the cathode-ray tube receives, and as this signal is originally derived from the impulses from the camera tube, the light and shade of the line varies according to the light and shade of the corresponding line of the scene which the camera is viewing. In this way the original picture is re-assembled spot by spot and line by line. At the end of each picture or "frame" the frame-synchronising pulse deflects the electron beam back to the top line, so that it is ready to trace out the succeeding frame.

The size of the picture in direct-viewing receivers is, therefore, governed by the size of the cathode-ray tube, and the larger tubes are rather costly. However, to meet the demand for large pictures a different type of receiver, known as the "projection" receiver, was produced. In this a very small cathode-ray tube is used, but one which produces a very bright picture. The light from this is passed through an optical system of mirrors and lenses and thrown on to a translucent screen. In this way the viewed picture on the screen has an area very much larger than that on the actual tube. The increased demand for the larger cathode-ray tubes has, however, led to a decrease in their price within the last few years, so that the projection system is not now so common in domestic television receivers.

The above description of the elements of the television system is, of course, a very brief and simplified one, and there remain several aspects and developments of television that we can do no more than mention. The technique for covering outside television broadcasts, for example, is highly developed in this country, though it follows, in general, along the lines of that described for giving broadcasts from the studio. On the Continent standards different from the British 405-line pictures are in use (441, 625, and 819 lines per picture), and this fact has complicated the international exchange of television programmes. Nevertheless, the B.B.C. has developed means for overcoming this difficulty, and in 1952 pictures from the French system were relayed by the B.B.C., whilst the B.B.C. television broadcasts of the Coronation were relayed over the systems of several Continental countries. Frequent exchanges of television programmes with countries on the Continent now take place, and the first part of a permanent television link between London and Europe—a two-way co-axial cable link between London and St. Margaret's Bay—is already in use. The differing television standards used in Great Britain and on the Continent necessitate "standards conversion" equipment to change, for example, a picture on the French 819-line standards to the British 405-line standards. The solution of this problem

by the B.B.C.'s Research Department as long ago as 1952 made these international exchanges possible.

The B.B.C. has also developed, within the past twelve months, a method of transmitting film pictures across the transatlantic telephone cable so that news shots, for example, can be seen on television within a much shorter time than would be required to fly the films across the Atlantic.

RADAR.

Historical.—In September 1939 Britain's Fighting Services already had in regular operation a new radio technique, by means of which it was possible to detect the approach of hostile aircraft, to plot their positions, and to follow their movements, and by the aid of which the defending forces could be rapidly brought into contact with them. Though the principles of this device were well known abroad, Britain was the first country in the world to evolve a practical system of radar and to put it into regular operation.

The original English name for the technique was "Radiolocation," a term which well describes the process, but during the war the "synthetic" word "Radar" was adopted from America, a word which we are given to understand is derived from the phrase "*RA*dio *D*etecting *A*nd *R*anging."

As in the case of so many of the inventions primarily developed for the purpose of waging war, many useful applications have been found for radar in times of peace, and, in particular, it has proved of great service as an aid to aerial and marine navigation.

The basic principle of radar is very similar to that of sight. We switch on a light in the dark, and we *see* an object because the light waves are reflected from it and return to our eye, which is able to detect them. Similarly, the radar station *sees* an object because the invisible radio waves sent out from the transmitter are reflected from it and return to the receiver, which is able to detect them.

The utilisation of radio waves for the detection of reflecting surfaces began with the classical experiment of Dr. (now Sir) Edward Appleton in 1925, which he conducted in order to demonstrate the existence of the Heaviside layer in the upper atmosphere. Then two American scientists found a somewhat different way of doing the same thing—they sent short, sharp "pulses" of radio energy up towards the sky, and found that the Heaviside layer reflected them and sent them down again so that they returned to earth as echoes.

The development of these methods of atmospheric-layer location into a radar system for the detection of smaller objects was only a matter of time, and in this country was placed in the hands of a team of scientists headed by Sir Robert Watson Watt. An experimental station was set up on the East Coast, and soon it became possible to see, on a cathode-ray tube, a clear image of an aircraft flying many miles beyond the range of ordinary vision, and to determine with good accuracy its position in space. Next the process had to be reduced from a scientific experiment to a common routine measurement, capable of being performed by relatively unskilled personnel, whilst equipment had to be produced capable of standing up to the wear and tear of continuous operation under Service conditions. As has been said, all these things were accomplished before war began, whilst during its course developments took place which tremendously improved the methods and instruments used.

Principles.—The essential difference between radar and the older methods of radio position finding is that with radar no active co-operation on the part of the located object is required. Radio waves are sent out from the radar station and, being reflected or scattered by the object whose position is desired, some of them are returned to the radar station, which is then able to tell the direction and distance of the object from which they were reflected, and, in the case of an aircraft, the elevation angle as well.

All that is necessary for this to happen is that the object to be located shall be of a material possessing different electrical properties from those of the medium surrounding it, in which case, when a radio wave impinges on it, part of the energy is scattered at the surface of the new medium. What happens is that the wave sets up electric currents in the material, and these reradiate energy, so that the new material behaves like a small transmitter. Fig. 7 will help to make the matter clear. Note that the reflected waves

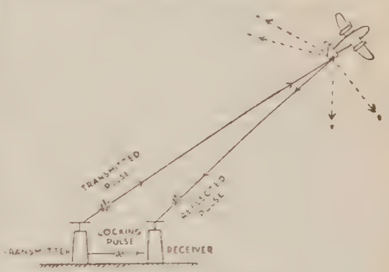

Fig. 7.—Radar System.

go out in all directions, but that some part of the energy is returned in the direction from which the wave has come. It is thus received at the radar station again, and from it is obtained the desired information about the object from which it was reflected.

A radar station consists of a transmitter and receiver working usually on centimetre wavelengths, and employing directional aerials which concentrate the radiated energy in the form of a sharp beam. The transmitting aerial can be swept around so as to cover different azimuthal and vertical directions, and the receiver aerial also sweeps around so as to receive only from the direction in which the transmitted beam is being sent.

The energy is sent in very short bursts called "pulses," and the receiver output is connected to a cathode-ray tube, upon whose screen the received pulses appear, as in Fig. 8. It is so arranged that as a pulse is sent off the fluorescent spot starts its sweep from the left of the tube, at *O*.

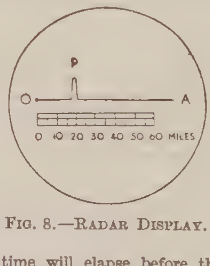

Fig. 8.—Radar Display.

A certain time will elapse before the reflected pulse is received, during which time the fluorescent spot is moving to the right (towards *A*) at a certain speed, and a bright line therefore appears on the screen. When the reflected pulse is received it is made to produce a deflection of the spot such as will produce a pattern like *P* in Fig. 8, and the position at which the pulse appears, as measured from the left, depends upon the time taken for the pulse to travel to the "target" and back, in other words upon its distance away. As we know that the speed at which the pulse travels is substantially 186,000 miles per second and as the speed at which the spot travels is also known, its sweep across the tube can be marked in a scale

of miles, and the distance of the "target" read off directly.

The distance thus indicated is only one of the pieces of information necessary in order accurately to plot the actual position of the target. It is necessary also to ascertain its direction or azimuth, and, if the target be an aircraft, its angle of elevation above the horizontal, as well. The means for obtaining these vary somewhat with the wavelength used, but in most modern radar installations they are determined by training the receiving aerial most accurately in the direction from which the received pulses are coming, a fact which is indicated by maximum deflection of the spot on the cathode-ray tube. Then the azimuthal direction and angle of elevation are read off from horizontal and vertical scales, and, the range being observed from the position of the pulse along the tube, the position of the target in space is given.

FIG. 9.—THE DISPLAY SCREEN OF A SHIP'S "RADIOLOCATOR" PRODUCED BY THE MARCONI INTERNATIONAL MARINE COMMUNICATION CO., LTD.

The ship is in the Straits of Messina, its position being indicated by the white dot, and its direction of heading by the white line.

Radar Developments.—The above is a brief outline of the basic principles of radar, and of its use in determining the position of a distant object, such as an aircraft or ship. Many variations and developments of the original idea have taken place, some of which have tremendously useful applications of a peace-time character One or two of these may now be mentioned.

Quite early there was developed a special type of cathode-ray tube known as the "Plan Position Indicator" or P.P.I. In this the fluorescent spot is caused to start in the centre of the screen and to sweep outwards to the edge, but at the same time to revolve about the centre so that it covers the whole screen perhaps twenty times a minute. Used in conjunction with aerials which rotate in synchronism with the spot, this causes located objects to appear on the screen in their true position relative to that of the radar station, whose position is represented by a mark at the centre of the screen. Fluorescent screens with a long "afterglow" are used, so that the brighter spots indicating the located objects persist on the screen until the spot sweeps over them again.

A further development of this idea takes the form of a compact radar equipment for use on ships or aircraft, by means of which a kind of television picture of the area surrounding the ship, or that below the aircraft, is shown upon the screen of the cathode-ray tube. As fitted on ships the equipment consists of a radar transmitter and receiver working on centimetre wavelengths, with a small aerial which radiates a beam of energy and which rotates in synchronism with the fluorescent spot of the P.P.I. tube. As the aerial rotates the beam sweeps over a large circle of territory corresponding to the size of the screen of the tube, the centre of which represents the point at which the ship is located. Anything that stands well up above the surrounding territory sends back strong reflections, whilst flat portions do not. Thus the surrounding sea appears black on the screen, ordinary level soil sends back weak reflections which cause the screen to glow faintly, but buildings and other structures, coast-lines, ships, and other outstanding features send back strong reflections and the tube glows brightly. Since the receiving aerial is at any instant "seeing" only that part of the landscape being illuminated by the beam, and since the fluorescent spot is, at the same instant, moving over the appropriate part of the screen relative to the ship at the centre, every reflected echo appears at the correct position upon it. Thus a "map" of the surrounding territory appears upon the screen showing all the prominent features of the landscape. It may be imagined how useful this can be in marine or aerial navigation, for it enables the navigator virtually to see through darkness or through fog, and to observe with clarity those objects surrounding him which are dangerous to navigation under conditions when they would otherwise be totally invisible to him. This apparatus is of particular use when approaching or traversing a tortuous channel or estuary, and furthermore, since it permits of the observation of other mobile objects, it is of great help in the avoidance of collisions. Fig. 9 depicts the sort of display which appears upon the radar screen of a ship proceeding up a restricted channel, the instrument in use being the Marconi Company's "Radiolocator," and the ship's position being indicated by the dot in the centre, and its direction of heading by the thin white line.

Great use is made of radar in the control of civil aircraft, both for the surveillance of aircraft flying along the airways between one region and another and also in the control of their approach to airports. A Marconi high-power radar installation working on a wavelength of 50 centimetres can perform either or both of these operations, since it can observe incoming aircraft to touchdown and outgoing aircraft from take off, and has a distance range of 100 miles. It is a dual trasnmitter/receiver installation, either unit of which can be switched to a common radar aerial, which is rotatable, and which is capable of being remotely controlled from an Airways Control Centre.

A further class of navigational aids has been developed, and is now widely used, which, though not actually working on the radar principle, may conveniently be mentioned in this section. In these systems the aim is to produce, in one way or another, a radio "pattern" over a wide area, so that the ship or aircraft can, by observation of the radio signals, tell at which point in the "pattern" it lies, and so fix its position upon a chart or map. As an example of this class of radio navigational device we may mention the "Decca Navigator," an apparatus by means of which the geographical position of a ship or aircraft may be found instantaneously at any time. The system here is for several synchronised transmitting stations on shore continuously to emit unmodulated waves, which, because of the interaction between the waves from the separate stations, produce a "space pattern" over the adjacent land and sea territory which is recognisable by instrumental means. Thus the waves from two such stations can be made to interact, so as to produce a series of maxima and minima, which take the form of curved "lanes" running across the line joining the two stations. An instrument on the ship somewhat like an ordinary electricity-meter continuously records the maxima and minima passed through as the ship moves along, so that when consulted by the navigator at any given time it tells him the number of the "lane" which he is in. A third transmitter, whose waves also interact with those from the first, produces another independent pattern of "lanes" which criss-crosses the first pattern, whilst a second instrument on the ship continuously records the ship's position in this pattern, and tells the navigator the number of the "lane" he is in within the second pattern.

Actually the "lanes" are divided into numerous subdivisions, which are indicated by the numerical indications of the two meters. In order to fix his position the navigator merely reads off the number indicated by the first meter and that indicated by the second, and then looks for the two correspondingly numbered lines in the two criss-crossing patterns on the chart. The point of intersection of these two lines is the ship's position. It will be appreciated that the above is a simplified description of the working of this system, and that various details have been omitted. It is easy to see, however, that such a continuously recording navigational aid is of great use in ships and aircraft, especially under conditions of fog or darkness, for it enables the position to be ascertained at any time with considerable accuracy, and independently of the ability to observe the usual navigational aids, such as lights, buoys, the sun, or the stars.

A recent development of the Decca system is the "Flight Log," or, for marine use, the "Marine Automatic Plotter." With these instruments the "pattern" of interacting waves from the Decca stations as just described is made use of, but, instead of it being necessary to read off the indications of various meters in order to find the position, this is continuously plotted upon a roller-mounted chart by a plotting pen. Thus, not only is the position of the aircraft or ship instantly indicated, but a continuous record of its track is continuously available.

In the fishing industry the high navigational accuracy of the Decca system is made use of in the location of shoals of fish, the grounds where these lie being approached exactly by the use of the system and the fish then being "spotted" by echo-sounding.

It will be seen, therefore, that a ship fitted with radar by means of which it is able to "see" the main features of the surrounding territory, with the addition of an aid like the Decca Navigator by means of which its position is accurately indicated at any time, is able to navigate through darkness and fog with almost the same security as would ordinarily apply under conditions of clear visibility. Thus has radio, apart entirely from its value as a means of communication, continued to prove a boon to the seaman and the airman.

Radio Astronomy.—The relatively new science of radio astronomy makes use of radio apparatus and techniques for the observation of events occurring in far distant parts of the universe, and, in so doing, is able to enlarge upon the observational field of optical astronomy in a remarkable way. By means of radio telescopes it is possible to observe parts of the universe so far distant that the radio waves received have taken thousands of millions of years to travel from their source to the earth, and thus to observe happenings which may have occurred near the beginning of the history of the universe.

There are two main types of radio telescope. The first, known as the interferometer, uses aerials spaced at large distances so as to cover a wide tract of ground. This has a high "resolution" but suffers from the disadvantage that it can "observe" only a very limited area of the sky overhead, as the earth turns upon its axis. The second, and "steerable," type, is that of the radio telescope at Jodrell Bank, Cheshire, which consists of an enormous concave metal bowl, with the radio aerials at its centre. This, though it has a lower "resolution," can be directed or "steered" on to any part of the sky which is above the horizon, and so can undertake a much more comprehensive observational programme. It can be used either to receive radio waves coming from desired sources or to transmit them and then pick up the echo from, for example, the moon or a planet, as in radar.

One source of radio waves which can be detected by radio telescopes is our own sun, whose behaviour under "quiet" and "abnormal" conditions can be observed in this way. Some of the planets also appear to emit radio waves from parts of their surface. But much more remarkable are the waves which are received from the so-called "radio stars," some of which are in the Milky Way, but others of which are situated in much more remote galaxies. It will be appreciated, therefore, that radio techniques are a powerful tool for the study of the universe, and that radio-astronomy is of great importance in modern science.

Tracking and Reception of Information from Satellites.—An important recent application of radio and radar is in the tracking and reception of scientific data from man-made satellites which have been put into various orbits by rocket propulsion from the earth. It is important, in the first place, to be able to follow the satellite in its orbit in order to interpret correctly the information received from it. One way of doing this is constantly to observe the direction from which the radio signals sent out by the satellite's transmitter are coming, by the use, for example, of the Jodrell Bank radio telescope. Another, which is of special use in cases where the satellite transmitters have ceased functioning, is to use such an instrument as a radar apparatus, and so to follow the course of the satellite by means of the radio-echoes received from it. The tracking of satellites can, of course, also be performed by the use of radar and radio receiving apparatus of a less-complicated kind than the Jodrell Bank radio telescope.

The scientific data which is recorded in the satellite, and which may be of many different kinds—ranging, for example, from the density and temperature of the atmosphere to the number of corpuscles of various kinds being encountered—is sent back to earth by a process known as "telemetering." In this the observations made are arranged to "modulate" the satellite's radio signals in a certain way and in accordance with a predetermined code, and the data are extracted from the received signals by decoding this modulation. As many as six sets of observations may be modulating the signals during any particular flight. Photographic and television techniques may also be employed for obtaining the desired information and sending it back to earth, as in the case of the recent Russian picture of the reverse side of the moon, and, again, the information may be stored within the satellite for a time, and then, upon receipt of a particular radio signal from the earth, may be transmitted by the satellite at a time convenient for its reception. Already man's knowledge of what surrounds this planet in space is, by this means, being revolutionised, and many interesting discoveries, such as those of the Van Allen radiation belts, have already been made.

Poultry and Pigeons

Poultry and Pigeons

By Dr. W. P. BLOUNT

ANCESTRY OF THE DOMESTIC HEN.

Perhaps the best question to ask in order to get an idea as to the place of the hen in nature is the old one about "which came first, the hen or the egg?" This is because a semi-scientific reply immediately puts one into the picture by recalling that birds are very closely related to reptiles; and it would not be too great a stretch of the imagination to suggest that it was probably a reptile's egg which really began the development of the class of animal we now call birds (*Aves*).

There are in fact fossils dating back to an era at least 50 if not 150 million years ago, of reptilian-birds; animals which can be considered intermediate between the true reptile and the true bird. Animals apparently developed from a reptilian framework, yet having "wings" covered by feathers, a very long feathered "tail," and "teeth." Over a period of hundreds of thousands of years there appeared the necessity for the reptile to adapt itself to flight—hence the growth of wings and, of course, the change from a horny type external skin to one consisting of feathers. Egg production is also a common feature to this group of animals, although of course reptiles are divisible into those producing true offspring (viviparous) and those laying eggs (oviparous).

In contrast with the eggs of fishes, those of the reptile and bird are covered by a hard outer shell to give protection against evaporation—a feature unlikely to occur in the case of eggs laid by fishes. One sees therefore a wonderful adaptation by nature—the fish swimming freely in water; the amphibian frog commencing life in water, passing through the tadpole stage to the frog proper, and ending its life on dry land. Thence to the reptile, at home both in the water and out of it, with its adaptation later to tree life involving the appearance of "flying" or perhaps only "gliding" reptiles. Finally, the development of birds as we now know them.

To-day therefore we accept the existence of *Archæopteryx* the fossilised reptile-bird as being definitely related to the ancestry of birds generally. Amongst living birds we have those which have only a miniature breastbone and are therefore incapable of flight, *e.g.*, the ostrich; and the remainder are the *Carinatæ*—birds with a well-marked keel. And chief amongst the many *Orders* concerned in *Aves* (birds) are: (*a*) *Galliformes*, *e.g.*, domestic fowl and turkey; and (*b*) *Anseriformes*, *e.g.*, the duck and goose. It is worth noting that the pheasant and peacock, which belong to the same Order as the hen, may all suffer from certain common diseases, *e.g.*, Blackhead. As a contrast the duck tribe appear resistant to this ailment, and for all practical purposes they are also immune to the Fowl Paralysis complex.

BRITAIN'S POULTRY INDUSTRY.

Poultry were for many years the hobby of the back-yarder, being valued for their brightly coloured feathers and general conformation. Our poultry industry developed through such fanciers, and there are now some millions of hens on general farms, but the fancier still exists however, his interests being maintained largely by shows.

The poultry industry began because of demands by the housewife for eggs and table poultry, and her special requirements and those of hotels must always be given first consideration.

A study of poultry has shown that some are best fitted for egg production, others producing meat more economically, but dual-purpose breeds or crosses are also available. There are, therefore, three main aspects to our present poultry industry: (1) the pedigree breeder; (2) the commercial producer of eggs intended for the housewife and bakery; and (3) the rearer of table poultry particularly broilers, which now number many millions. The fancier has successfully maintained the external appearance (conformation) of his different breeds, but it is only as a result of studies based on economics that we have discovered those breeds and strains best fitted for either egg or table poultry production.

The development of the industry to its present state, now comprising over 90 million head of poultry, has been achieved only by means of hatcheries, where thousands of eggs are received each week and incubation carried out in large, mammoth machines. The day of the broody hen has long since disappeared, except when very small numbers of chicks are being hatched. The domestic poultry keeper usually keeps half a dozen or more birds to provide eggs for his household, and a few cockerels may be reared for festive occasions. He is, however, not advised to undertake the breeding or rearing of day-old chicks unless well experienced in these subjects.

Breeds.—For *egg production* the R.I.R. is our most outstanding breed, but there are many good strains of Light Sussex, Wyandottes, and Buff Rocks (among the heavier breeds), the Leghorns amongst the light breeds. Many cross-breds are equally suitable, with certain light-heavy crosses outstanding in this respect.

RHODE ISLAND RED PULLET.

Hybrids.—A comparatively new development has been that of commercial *hybrids* for egg production, and whilst the earlier examples of this type of bird were the result of crossing inbred lines—incrossbreds—more recently recurrent reciprocal selection has been used as a basis for their breeding programmes. The advantages of hybrids are that they are more uniform than standard-bred stock, and their average egg production is also higher. Their mortality rates differ, however, some being quite susceptible to the avian leucosis complex, whilst others are resistant. Well-known examples of to-day's hybrids are: Sterling's "Gold, Silver, and Red-Links"; Thornbers "404–505"; Fairbairn's "Hy-cross"; Evan's "Maxilay", etc. Already some of these hybrids have won high awards at various Laying Trials. As they can be "mass-pro-

duced " easily, some are already being marketed by the million. As a result many fewer pure breds are now being sold for commercial egg production, although the largest competitor to the hybrid is still the light × heavy crossbred, particularly the Wh. Leg. × R.I.R. and Br. Leg. × Lt. Sx.

For *table poultry production* the Light Sussex is ideal, because of its splendid conformation and plentiful supply of both breast and leg meat also its white skin and legs. The housewife unfortunately has a prejudice against yellow-legged breeds, although the taste and quality of their meat is just as good as that from the white breeds. Lt. Sx. crossed with R.I.R., W. Rock or Ind. Game are very popular, also New Hamps. and N. Holl. Blue.

The *pedigree breeder* maintains his breeds in pure form, and is able to identify his chicks and relate them to their parents. His is an exacting task, for he is particularly concerned with the intricacies of fertility and hatchability. The pedigree breeder is not able to provide sufficient stock for sole use commercially, but as a result of his work pure-bred cockerels can be mated to non-pedigree pullets and the resultant chicks used for commercial purposes.

LIGHT SUSSEX COCKEREL.

The Ministry of Agriculture, Fisheries, and Food sponsor a scheme of *Accreditation* for those poultry breeders who are prepared to conform to certain regulations. These comprise compulsory blood testing (for B.W.D.), the keeping of essential records, farm inspections, etc.

These accredited poultry farms and hatcheries are all part of the Ministry's Poultry Stock Improvement Plan (P.S.I.P.), and comprise farms where special precautions are taken for the prevention of disease and where there is a high standard of management under the supervision of the Ministry's advisory officers. The names and addresses of those who have been accredited are published, county by county, annually in a register. It is hoped that this will enable poultry keepers to know from where they can buy stock with a minimum risk of disease and with a reasonable measure of security regarding the quality, health, and vigour of the parent stock. It should be appreciated, however, that accredited stock are no more free from Fowl Paralysis than other stock, nor are they any more resistant to such diseases as Fowl Pest (Newcastle Disease), Coccidiosis, Nephritis, etc.

SYSTEMS OF POULTRY KEEPING.

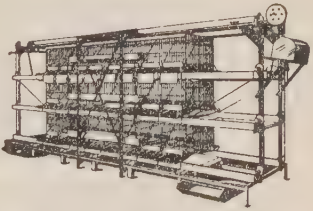
The tendency to-day is for poultry to be kept *intensively*, that is with no opportunity to get out on to grassland, and the three main systems are: (*a*) Hen Batteries; (*b*) Deep Litter; and (*c*) Hen Yards.

Hen Batteries.

Here birds have their own cages, which are arranged in tiers, usually three high, and each pullet has its own individual food and water trough. The birds can be seen separately at all times, and it is, therefore, possible to decide whether or not they are paying for their keep. They are free from attacks by foxes and rats, and do not suffer from those diseases contracted by running over infected ground, *e.g.*, Tuberculosis. Their main disadvantage is the initial cost of the cage which varies from 18*s*. to 24*s*. This is compensated for by their better average egg production and the opportunity this system gives to the poultry keeper for culling. (Culled birds are those which do not appear to be profitable.) There is also the fact that after laying for one year in batteries, pullets can be sold at a premium, for laying stock kept intensively in this way are fatter (internally) and their flesh is very tender. Hen batteries are not cruel, because the birds eat well, lay well, " talk " contentedly, and do not suffer from many diseases which affect stock housed on other systems, *e.g.*, Worms and Coccidiosis. Mortality averages 13%.

Twin-bird hen battery cages, each of which holds two birds, are popular nowadays because of the considerably reduced capital expenditure. It is important that such birds are fed on dry mash *ad lib*. Bullying may develop in a few cases, but this can be avoided by selection of stock, or by the use of spectacles or de-beaking.

Hen batteries to hold from three to six pullets are now also being marketed, and even larger ones holding up to twenty birds have been tried out. Results generally have been satisfactory, but attention to ventilation is important. In general, it is necessary to de-beak any pullets which are being housed three or more per cage *before* they are put into the batteries, as this overcomes any tendency there may be to fighting. Their feed should always consist of a balanced " Hen Battery " mash or crumbs (" chips "). A supplement of pellets assists feed intake when mash is used.



SWIFTS CAFETERIA HEN BATTERY UNIT.

Cafeteria-type battery cages in which the food and water troughs travel up and down or around the cages are also marketed in this country. They are very labour saving, and one man can look after 2500 to 3000 birds on this system. It is important that the birds are given a minimum of fourteen hours' feeding time.

Special cages for domestic poultry keepers and for the keeping of bantams are sold, and the former can be arranged so that the birds are kept out of doors the whole time, but winter production will not be high unless specially good birds are chosen. Under B.O.C.M. laying-trial conditions at Stoke Mandeville egg production (forty-eight weeks) in hen battery cages was as follows:—

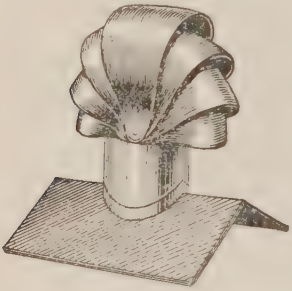
	Average Egg Production: Team.	Highest Egg Production: Bird.
Ducks . .	191	320
Pullets . .	201	309
Bantams . .	108	220

Food consumption (pellets) per bird per day averages:—

Ducks	4–8 oz.
Pullets	4–6½ oz.
Bantams . . .	2–3 oz.
Turkeys . . .	5–10 oz.

Deep Litter.

The deep-litter system, introduced successfully from America, makes use of any intensive type poultry house; but the more insulation provided by the walls and roof of the building the better. The object is to build the litter higher and higher, during which process heat is produced by the decomposition of the droppings from the birds. This gives rise to some ammonia, but the heat also dries out the litter. In other words, the birds are kept dry and warm, but special ventilation is necessary to dispose of the moisture vapour and ammonia which are natural by-products of this system. It is very labour saving, and one man can look after several thousand pullets, probably twice as many as kept in batteries. To maintain egg production, particularly in the winter months, a generous ration of balanced feed is essential, and there should be from 4 to 6 in. of hopper space per bird. Where large numbers



"ASHANCO" TYPE FIXED-EXTRACTOR COWL.

of pullets are kept in one house (*e.g.*, 750) an automatic feeder is economical as well as automatic water devices; and instead of using single nests a communal type nest—measuring 5 ft. × 2 ft per fifty pullets saves labour but encourages broodiness. Unless attention is paid to the ventilation arrangements, the litter will get wet in the winter-time, and moisture will condense on the roof, iron girders, windows, or other cold surfaces. This leads to the production of dirty eggs. To keep the birds occupied—so that they do not develop vices from boredom—supplementary feeds of pellets or corn are advisable.

Mortality is but little greater than that of hen batteries, but should any infectious disease break out it will spread rapidly throughout the flock. "Colds," worms, and intestinal coccidiosis are the chief diseases which attack birds kept on deep-litter. "Pullet-Disease" and nephritis may also prove serious.

The type of material to use for the bedding of deep-litter houses varies from sawdust to peat moss, but in general it is the cheapest product available which should be used. Wood shavings or chopped straw are excellent, and except when peat moss is expensive the foundation for good deep litter should consist of 1 in. fresh horse manure, 2 in. wood shavings, 2 in. chopped straw.

The speed with which the litter "works"—that is the production of heat—depends upon the number of birds per given area, the depth of the litter, the time of year, drainage, house construction, etc. In general deep litter is easier to start in the warmer summer weather; when the birds are given a droppings pit (to keep the night's droppings away from the litter of the house proper), and when each bird has not more than 3 sq. ft. of floor space apiece. Long straw does not break down as satisfactorily as short, cut straw; and sawdust is not as good as wood shavings, but all these materials can be used if needs be, as well as chaff, husks, etc.

The bacteria and fungi which are responsible for the heat and ammonia produced under built-up litter conditions also synthesise certain nutrients which are of value to poultry, *e.g.*, vitamin B_{12} and vitamin B_2 (riboflavin). It is, however, not a good plan to rely upon this as their sole source of water-soluble "B" vitamins. Balanced feeds containing these and the other vitamins necessary for health and production should be used; for breeding stock special rations are available.

It will be appreciated that when poultry are kept confined on deep litter for any length of time there is often a build-up of bacteria, parasites, worm eggs, coccidia, etc., which may eventually prove harmful. For this reason it is not recommended that the same litter should be kept going from one batch of *chicks* to the next (as in broiler production) unless it has been "heated." This is accomplished by piling the litter into as large and as high a heap as possible and letting it remain heated for about four days. (The internal temperature of the heap should exceed 130° F.). For laying stock the litter can remain throughout the full laying season (*i.e.*, 11–12 months), unless coccidiosis or worms have appeared.

Hen Yards.

The hen-yard system is really an adaptation of the deep-litter system to that of the old-fashioned semi-intensive method of keeping poultry. A small house (with a droppings pit and communal type nest) providing about 2 sq. ft. per bird is supplemented by a yard twice this size. As a contrast to the semi-intensive system, the yard is covered by straw, which is gradually built up throughout the winter months. Grain feeds can be scattered on top of the litter each day, but continuous dry-mash feeding is essential to help to prevent feather pecking and cannibalism. This is the cheapest system of housing layers, and many old farm buildings can be adapted for this purpose, but egg production is usually somewhat inferior to the other two systems mentioned.

The true *semi-intensive system* of housing birds, in which they have access to both a house and run, has become much less popular because of the incidence of disease; for maladies such as Worms, Coccidiosis, and Fowl Pox are liable to be encountered year after year with this method of keeping poultry.

Colony Houses.

When poultry are kept on pasture in small (colony) houses this is sometimes termed *the extensive system* of poultry keeping, and in order to avoid any build-up of disease the houses are moved about 25 yd. each week. They are less satisfactory for winter egg production, and much time may be spent washing dirty eggs.

Fold Units.

Fold units are an improvement over the use of colony houses, the birds being confined to small, portable, combined houses and runs, approximately 5 ft. wide by 18 ft. long. Each fold holds about twenty birds, and is moved its own length every day, and in this way the birds get fresh grass and exercise. Lighted "static" folds are very useful for improving winter egg production. Such portable units can also be used for breeding stock, but feather pecking, cannibalism, and dirty eggs must be avoided if the system is to be successful. Folds are best used on level ground, and the soil should be sand or gravel—not clay.

Area Requirements.

On the free range (extensive) method of keeping poultry only about 75 to 100 birds are allotted per acre of ground, *i.e.*, about 60–70 sq. ft. per bird; whereas on the semi-intensive system 200 birds per acre is normal (20–25 sq. ft. per bird). In folds each bird has about 5–6 sq. ft., which is the same amount as that allowed for hen yards.

In deep-litter houses 3½–4 sq. ft. for heavy breeds and 2¾–3 sq. ft. for pullets of the light breeds is usual, contrasted with 2¼ sq. ft. for hen batteries. (In twin-bird batteries, of course, the area is reduced even further.)

These facts show how modern methods of housing have economised on ground (or floor space) without deterioration in health or loss of egg quality—provided that the food given to the birds is "balanced," *i.e.*, complete in vitamins, minerals, trace elements, etc.

Advisory Services.

Many of the larger compound feeding-stuffs manufacturers (*e.g.*, B.O.C.M.) have their own advisory service comprising qualified field staff, veterinarians, etc. The Ministry of Agriculture's National Agricultural Advisory department (N.A.A.S.) also consists of personnel specially qualified to advise farmers on matters of husbandry, nutrition, disease control, etc. Enquiries should be addressed to the Chief Poultry Officer, Ministry of Agriculture, Fisheries, and Food, Horseferry Road, London, S.W.1 (Vic. 8511).

INCUBATION.

If the temperature surrounding fertile eggs is raised to about 100° F. and maintained there for about twenty-one days they will hatch, provided the eggs are "turned" several times daily and the humidity kept within certain levels. This in fact is what happens when a broody hen sits on fertile eggs, but for commercial purposes artificial incubation is preferable if only because mammoth machines have now been manufactured capable of dealing with thousands of eggs instead of a mere ten to fifteen as in nature.

Broody Hens.

Broody hens, of course, are perfectly satisfactory for incubating small clutches of eggs, but they should be de-loused and de-wormed and examined for Pox and tested for B.W.D. before use; and also tried out with pot eggs before being given fertile eggs. Heavy breeds are often broody, but non-broody strains are available. Light breeds seldom go broody; crossbreds vary greatly.

Broodies require to be removed from their eggs only once daily for 15 minutes' exercise, feeding, and watering. After hatching takes place the hen and her chicks are best kept in a coop for two to three weeks before being transferred to more commodious surroundings.

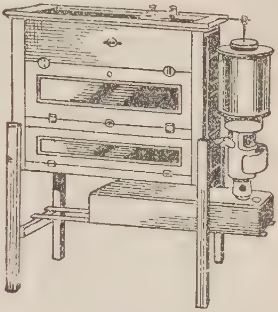
To improve on the hatching results obtained from broody hens, great advances have been made during the past century, although exceedingly good results from the incubation of large numbers of eggs were obtained, and still are, by the Egyptians, who use "ovens." Charcoal fires provide the source of heat, the eggs being laid out in their thousands in ovens above. At about the fifteenth day the hot ashes are raked out, by which time the chick embryos provide sufficient residual heat for hatching to take place on the twentieth to twenty-first day. Whilst no accurate control over temperature or humidity is possible, the results are worth while, the whole process being both cheap and labour saving.

It is probable that Charles Edward Hearson (1846–1920) made the greatest single contribution to artificial incubation when he invented the thermostatic envelope ("Hearson's Capsule") in the eighties. Originally a pharmacist's assistant in Barnstaple, he left for London in 1865 to continue his studies in chemistry, physics, and electricity. A friend was visited in Surrey, and it was there that he saw a poultry farmer endeavouring to keep hatching eggs constantly warm by means of a water-jacketed box. After months of research Hearson devised a unique piece of apparatus for regulating the heat from a paraffin-oil burner, his first incubator having been made in 1875. His "capsule" became standard equipment on all hot-air and hot-water incubators for upwards of half a century, and it is still in fact being used in many type of incubators, both egg and bacteriological.

Until about 1920 the size of poultry incubators had purposely been kept small so as to hold only a few hundred eggs, but during the succeeding fifteen years many mammoth and cabinet incubators came on to the market, including one to hold 70,000 eggs exhibited at the British Industries Fair, London, in 1933. Later developments included the provision of separate setting and hatching compartments, automatic (hourly) turning, large built-in brick incubators, electric alarm bells etc.

Fertility.

Poor fertility can result from defects in either the cock or hen, but it is also related to management. Most cocks and hens are fertile, but a small percentage are genetically defective. If the male is subjected to very cold weather and his comb becomes frost bitten fertility will fall sharply; it will also be poor if he has too many females with which to mate. If mating takes place at only infrequent intervals fertility deteriorates. Matings should take place at not more than seven-day intervals for cocks, for turkeys the period can be extended to 2–3 weeks. The diet of breeding stock should be "complete," as for hatching purposes, or fertility will be impaired.



Paraffin-oil-heated, Hot-air, Small-size Incubator.

The implantation of stilbœstrol or other selective female sex hormone (as in chemical caponisation) into cockerels causes a severe temporary loss of male characters, and infertility also results. After about eight weeks it returns, and it may be normal again in one or two months' time. If hatching eggs are held longer than seven days fertility begins to fall, parallel to the length of the storage period, particularly if the temperature of the room is either too high or too low. Certain maladies, such as Newcastle Disease, also cause a marked temporary infertility in poultry. Nicarbazin in a breeder's ration also lowers hatchability.

Hatchability.

Hatchability is governed by breed factors and also by environment, and in this connection the most important single factor, apart from the actual incubation, is nutrition. It is the foodstuffs given to the breeding stock which must contain vitamins A, B_2, B_{12}, D_3, and E, and minerals (calcium, phosphorus, manganese), since these are all known to affect the development of the chick embryo. Hatching is, of course, governed by the ability of the chick to emerge safely from the egg in order to live its own independent existence, and this automatically implies that it must have been free from defects such as "crossed beak" and that both the shell and its membranes are sufficiently "softened" to allow the chick to emerge at about the twenty-first day of incubation.

Factors Affecting Incubation.

Storage of Eggs.—Hatching eggs are best stored broad end uppermost at 55° F.; if the temperature exceeds 80° F. incubation will start automatically. Storage temperatures below 35° F. should be avoided whenever possible.

If stored longer than seven days hatching eggs should be turned daily, but hatchability will deteriorate the longer they are kept; in any case it is unwise to keep them longer than 10–14 days.

Humidity should be quite high—between 80 and 90 per cent. Eggs received by train or lorry should be allowed to stand for twenty-four hours before being set, otherwise there is a risk of "tremulous air cell" developing.

Cleaning Eggs.—Eggs should *not* be washed

except using warm water at about 80° F. containing a detergent-germicide. Mechanical dry cleaning is generally preferred.

Incubation.—Be certain to run the incubator at the temperature recommended by the manufacturers—each make of machine may differ in this respect. In still-air machines the temperature at the top of the eggs is important, and if too high this leads to embryological deformities; low temperatures delay the hatch. In the event of an electricity cut keep the incubator room warm (90° F.) but open the machine every half hour or so to get fresh air into it.

It is not necessary to cool eggs—this is only actually necessary in small machines *for turning purposes*. Cooling itself delays hatching, and is to be avoided.

Humidity is very important as follows: Papworth machines require 55 per cent. relative humidity; Stephens 55 per cent. in the setter and 75 per cent. in the hatcher (when the eggs are pipping); Western 55–60 per cent.

If humidity is low it may lead to a parching of the membranes, which then offer a physical barrier to hatching. Too high a humidity is also wrong, because it interferes with embryonic development and can cause death-in-shell.

Correct *turning of the eggs* during incubation is very important, as it imitates a physiological process carried out by the broody hen herself many times each day. It prevents the embryo from "sticking" to the inner shell membrane, and also makes certain in small machines that the temperature of the egg is equally distributed. Improper turning is believed to be one important cause for chicks finishing with their heads at the small end of the egg at hatching time. Hatching eggs should be turned in small machines at least twice and preferably three times in twenty-four hours; in cabinet incubators they may be turned each hour mechanically. It is not advisable to turn eggs during the three to four days immediately prior to hatching.

The Ventilation of the incubator room is vitally important, and as much fresh air as possible should be circulated—to supply oxygen and to remove carbon dioxide and moisture—without creating draughts. This air should also be warmed, if practical, to 60° F. Consideration must also be given to removing the foul air by outlet cowls or vents at the top of the room. Incubators should not be placed in a corner of a room nor up against one of its walls, as this impedes air circulation.

Nutrition of the Breeding Stock.—Unless stock cockerels and pullets or hens used for breeding receive a balanced diet, hatchability will be poor. Firstly, they should not receive large quantities of bulky food such as swill, Tottenham pudding, or steamed potatoes. Secondly, their diet should contain at least 4–5 oz. of "breeder's" pellets or mash, rich in vitamins; together with 1 oz. of whole grain. (Unnecessary if the breeder's ration contains vitamin E.) Breeder's rations must contain adequate levels of those vitamins and minerals essential for the growth of the developing embryo, *e.g.*, vitamin B_2, B_{12}, etc. When not present in feed ingredients, supplements of these must be added at the time of manufacture.

Candling.—The method of testing eggs for fertility is known as "candling," and it can also be used for the determination of egg faults. The eggs are taken to a dark room or cupboard, where they are subjected to the bright rays of an electric lamp. Hatching eggs may be tested in bulk by lifting the trays over a special table with the electric light beneath it; the poultryman then marks the infertiles, which he subsequently removes. In the case of fertile eggs a small dark area can be seen as early as the fourth day, but candling is normally carried out on the seventh, tenth, or eighteenth days. In the case of infertile eggs they remain clear because of the lack of development of the embryo chick. When fertile eggs are tested on the eighteenth day the whole of the egg is dark except for the air space.

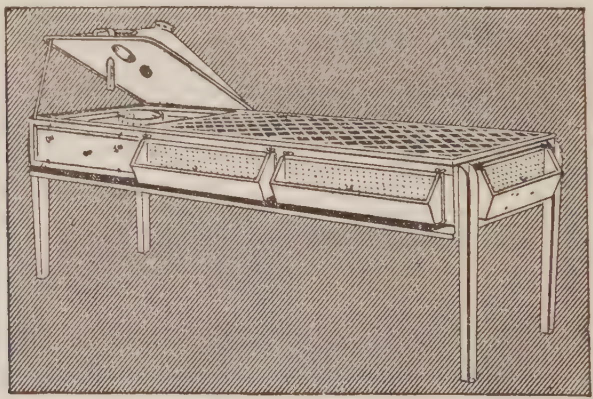
Fumigation of Incubators.—Due to the fact that large numbers of disease-producing germs may develop in eggs during incubation, and also because the "fluff" from newly hatched chicks may also be heavily contaminated with germs, it is important that incubators are thoroughly disinfected immediately after each batch of chicks passes through them. The common method is to add 1½ oz. of liquid formalin to ¾ oz. of potassium permanganate crystals (for each 100 cu. ft. of air space). A violent chemical reaction takes place, liberating large quantities of formaldehyde gas, which, however, is more effective as a disinfectant if the interior of the incubator is humid and damp. All exits should be sealed for one hour. Poultrymen using the method for hatching eggs must see that no eggs are fumigated between 24 and 84 hours of incubation, or poor hatchability will result.

It has recently been shown that concentrations of formaldehyde gas three times those normally used should be recommended when infection (*e.g.*, Salmonellosis) is known to be present. Thus 4½ oz. of 40 per cent. formalin is used per 100 cu. ft. of air space. For dispersing the residual gas, ammonia can be used.

Sexing Day-old Chicks.

The crossing of certain breeds, *e.g.*, R.I.R. cock × Lt. Sx. hen, results in chicks the colouring or pattern of whose down at birth readily separates them into two groups, male and female; This is termed sex-linkage, and the basis for such matings provides an interesting study for students of animal breeding.

The sexing of pure-breed chicks at day-old was



SINGLE-TIER TABLE BROODER FOR CHICKS.

ade possible in this country in 1934 following the scovery in Japan by Masui and Hashimoto of a ethod whereby the vent of a day-old chick is erted and a small vestigial genetical eminence amined. If completely absent the chick is a illet, those with an eminence are usually male, it a small percentage may be female. It takes i expert some two years to be able to sex all eeds accurately and speedily, *e.g.*, about a ousand chicks per hour; 95 per cent. accuracy.
In 1950 the Japanese again astounded the oultry industry by inventing a small instrument r insertion into the vent of newborn chicks in der to view indirectly the gonads by reflected ;ht, thus allowing the operator to decide whether ie ovary (on the left side) or two testes were esent. The former being typical of pullets and e latter of cockerels. This is a more accurate ethod than that originally used—98–100 per nt. frequently being obtained—and also easier learn. It takes only two or three months to quire a reasonable degree of accuracy, but the eed of the operation is little more than half that the ordinary vent-sexing method.
It should be noted that in neither the "vent" or the "machine" method are chicks damaged any way in the hands of efficient chick-sexing erators.
A British method for sexing chicks accurately as developed by Punnett and Pease at Cambridge niversity during the thirties, resulting in the roduction of "Auto-sexing" breeds based on own colour. The "Legbar," "Cambar," and Brussbar" are typical examples of the breeds ncerned, but as their economic qualities are ten inferior to those of the established pure eeds and crosses, the auto-sexing breeds have ot become as popular as was at one time expected.
Older chicks, aged four to ten weeks, can be xed as soon as they show distinctive sex charac- rs—*e.g.*, by the size of their comb and wattles, e shape of the bird's head and shanks, and also the appearance of the neck, saddle, or sickle athers.

CHICK REARING.

To-day very few chicks are reared under broody ens, partly because broodies are usually only ailable during a limited period of the year and so because unless chosen very carefully they ay spread certain diseases to their chicks. ore particularly, however, because to rear 100 iicks would require at least half a dozen broody ens, and these would not be easy to find at short otice, nor would they be easy to manage. Mod- n methods are such that 100 chicks can be ared to eight weeks of age *on the floor* of a room ft. × 12 ft., but in tier brooders a room of this ze might hold over 1000 chicks.

Requirements.

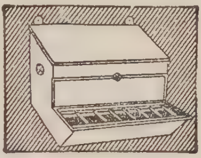
Artificial heat, food, water, bedding, and good entilation provide the essentials for chick rearing, it the skill of the poultryman is an equally im- ortant factor. Day-old chicks can be purchased -day in large or small numbers, suitably sexed— ckerels for table poultry and pullets for egg oduction—at a few shillings each, and as soon they are received they should be put under artificial foster-mother—a *hover*. Electric or fra-red ray lamps are very popular nowadays, ecause they need so little attention yet provide adequate source of heat. The temperature the level of the chicks' heads should be about ° F. during the first week; thereafter it can be duced gradually until the chicks are free from tificial heat by four weeks of age (five weeks in nter-time). Oil-heated hovers of circular and ramidal patterns are equally successful, but ains, "Bottogas," or "Calor" gas brooders are pecially popular in rural areas where there is no ectricity.

Ventilation.

No matter what system of brooding is adopted, e air in the room or compartment should be kept ite fresh, and if it feels muggy or creates a nsation of headache in the attendant something is wrong. Too often the amateur keeps the atmosphere too hot and also too dry—it is only under the hover that the air needs to be heated, elsewhere it can be quite cool, so long as there are no draughts. Cold air stimulates feathering, and also increases the appetite. The adjustment of windows is very important, and requires constant attention because of climatic differences from day to day. Electric extractor fans capable of supplying 1 cu. ft. of air per 1 lb. liveweight per minute are desirable.

Equipment.

Young chicks have little initial sense as to their ability to get warmed up under a hover, but they soon learn this by instinct if given assistance. For this purpose a metal or cardboard surround (15 in. high) about 3–4 ft. in diameter is invaluable during the first few days. Its use prevents chicks from straying, and in this way they quickly learn where to find heat, food and water.



FOOD HOPPER FOR CHICKS.

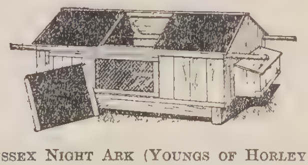
Food Hoppers should be such that chicks do not walk over the food, nor foul it with litter, etc. As soon as possible they should be raised on blocks of wood, or the feed will be constantly covered by litter scratched there by the chicks. Fresh supplies of food should be used daily, and sufficient hopper space allowed so that each chick has ample opportunity to feed. Allow 1 in. at day-old, 2 in. at 4 weeks, 3 in. at 8 weeks and 4–6 in. at point-of-lay.

Water Troughs must be large enough to hold a full day's supply of water and also be capable of being cleaned thoroughly. Water troughs should not be so large that day-old chicks can get into them, or they may drown.

For day-old chicks an inverted 2-lb. jam jar over a large saucer can be used in an emergency, but portable, inter-locking, two-piece water fountains are preferable. Provide 6 pints daily per 100 chicks at day-old, 2½ gallons at 5 weeks, and 5 gallons daily per 100 adults.

Housing.

Considerable skill is required when chicks are to be reared out of doors, and for this reason they are best brooded under hovers, on solid floors; or in tier brooders. By 4–6 weeks of age, however, when they should be fully feathered, they can be taken outside. Two of the best pieces of equipment for rearing pullets are the well-known Sussex Night Ark, and the Hay-box Brooder.



SUSSEX NIGHT ARK (YOUNGS OF HORLEY).

More recently portable Range Arks of a type used in America to hold sixty to eighty growing chickens have become popular. They comprise open-sided, low-roofed houses with perches and feed hoppers, etc.

Litter.

For bedding purposes a variety of materials are available, but peat moss, chopped straw, or wood

shavings are often preferable to chaff, coffee husks, or sawdust. A layer ½ in. thick should cover the floor, but its renewal will depend upon the risk of Coccidiosis, and unless replaced every day an anti-coccidiosis drug may require to be used in the feed or water. Many poultrymen are successful in building up the litter to a depth of about 4–6 in. (so-called "deep" litter), but considerable skill is required, or it will get damp and soggy and become a source of disease. Good ventilation and the use of splash-proof drinkers will help to keep the litter dry. It should also be turned regularly.

Feeding.

The system and method of feeding day-old chicks is vital to their success. *The first feed should be given at floor level,* below or near to the hover. A sheet of cardboard, or part of a feed bag, can be laid on the floor and the mash, crumbs, grain, wet mash, or whatever feed is being given scattered over it *as soon after the chicks have settled down as possible.* It is a completely mistaken idea to deprive chicks of their first feed for 24–48 hours, and the earlier they can get to it the better. A few ounces of food scattered over the floor in this manner will occupy the chicks during their first hour or two, until in fact they have learned where to find their ordinary food troughs. Chick box lids or Keyes trays make good temporary feeders, until wooden or metal troughs can be used by the chicks after about 48 hours. Supplies of fresh water alongside are equally important.

Note.

Even in the case of chicks being reared on wire floors it is still a good plan to give them an early feed, on paper, at floor level. After the first day more feed can be given on egg flats for example; this encourages the chicks to forage, during which period they will soon discover the site of their proper feed troughs.

Amongst the feed should be scattered some coarse sand or fine flint or gravel grit, because although this may not be actually necessary for grinding up the food in the gizzard it will prove invaluable should chicks attempt to eat some of their litter.

Some poultrymen insist that the first feed for their chicks shall be grain—groats, cut wheat, or maize grits—others prefer dry bran, but both practices are wrong. The feed should be "balanced," from both the growth and health standpoints, and this means a properly prepared ration which can be given as crumbs or mash—wet or dry. The greater the palatability of the feed (assuming it to be balanced) and the more food eaten the quicker the growth rate of the chicks. The following data taken from Stoke Mandeville trials refer to as-hatched stock:—

	Weights		
	Table Chicken (Broilers)	*Aylesbury Ducks*	*Turkey Poults* (B.B.B.)
	lb.	lb.	lb.
2nd week	0·36	0·76	0·75
4th week	1·0	2·75	1·44
6th week	1·70	4·5	2·88
8th week	2·75	6·1	4·22
10th week	3·50	6·8	6·50

Weighing Scales are necessary to check the progress of one's chicks, because a steady growth rate is essential for the successful rearing of poultry, no matter what the species. They should preferably be capable of weighing between 1 oz. and 10 lb., for they can then be used on any bird between day-old and three months, and they will be equally valuable for weighing food. If weights are known for both growth rates and the amount of food consumed, then a "feed conversion" factor can be obtained.

Feed Conversion is related to the particular strain of bird; the nature of the ration; the construction of the feed hoppers; the weather and housing. For example it takes 2½ lb. of feed per 1 lb. liveweight gain for 10 week chicken.

Food Consumption.

Assuming that poultry are being fed on balanced compounded feeds rather than swill, cooked potatoes, or other bulky feeds, their needs can be calculated from the following table:—

	Chicks	
	(1).	(100).
1–7 days .	1½ oz.	9½ lb.
1–14 days .	5 oz.	31 lb.
1–28 days .	1¼ lb.	1 cwt.
To 8 weeks .	6 lb.	5½ cwt.
To 16 weeks .	27 lb.	1 ton 4 cwt.
To 26 weeks .	35 lb.	1 ton 11 cwt.
1st Laying Year	1 cwt.	5 ton
	90–140 lb.	4 tons–6¼ tons

In the case of "light" breeds these figures can be reduced by one-fifth to one-eighth, and for t[illegible] heavy crosses increased similarly. Where gra[illegible] is being fed this should not replace more th[illegible] 15 per cent. of the chick ration. For growers a[illegible] layers it is best used in conjunction with a *Poul[illegible] Grain Balancer* ration.

POULTRY NUTRITION.

Rations.

Manufacturers of compound animal fe[illegible] usually offer the following balanced rations:—

1. "**Baby Chick**," intended for use from day-[illegible] to about four to six weeks of age; complete a[illegible] balanced in every way, such feeds do not requ[illegible] any grain, fresh greenfood, skimmed milk, or lime-stone grit. Baby chick rations are often avai[illegible] able in two forms, *i.e.*, as mash, and crumbs—th[illegible] latter is just as palatable as wet mash, but d[illegible] away with the extra labour involved in prepari[illegible] it. The continuous *ad lib* method of feeding [illegible] which the chicks help themselves is common[illegible] practised, because it satisfies the appetite a[illegible] saves labour as well.

2. "**Growers**" **Rations** contain less prote[illegible] and fewer vitamins than those intended for you[illegible] chicks, and are given to stock aged six to twent[illegible] weeks. "Growers" rations are complete i[illegible] themselves, but if grain is to be fed in any quan-tity, then a poultry "grain balancer" feed shou[illegible] be used instead. This is available as mash [illegible] pellets (⅛ in.), and although the former is oft[illegible] given *ad lib*, pellets are usually restricted to 1½–[illegible] oz. per bird per day according to age.

3. "**Layers**" **Rations** are also complete, a[illegible] it is a mistake to dilute them with grain, becau[illegible] egg production may then fall in proportion to th[illegible] amount of grain fed. (See next para.)

4. "**Poultry Grain Balancer**" **Rations** a[illegible] necessary because grain itself is unbalanced[illegible] being rich in energy, and low in protein a[illegible] vitamins, therefore, a special balancing ration [illegible] desirable. But not more than 40–50 per cent. [illegible] the total diet should comprise grain. This ca[illegible] consist of wheat, oats, or barley. All sto[illegible] receiving grain need regular monthly supplies [illegible] flint or granite grit. Limestone grit should [illegible] given to laying stock daily but not to baby chicks

5. **Hen Battery Mashes and Pellets** ($\frac{3}{16}$ in.) a[illegible] specially prepared for use by stock kept in h[illegible] battery cages, and they, too, are best used libe[illegible] ally and without any addition of grain. H[illegible] Battery Mash can also be recommended for u[illegible] by stock housed intensively, *e.g.*, on Deep Litte[illegible] but pellets are not recommended for continuo[illegible] feeding. (This is because with pellet feeding [illegible] full crop is obtained quickly, and the birds, havi[illegible] little to do, look around and may start pulli[illegible] out one another's feathers. This leads to unsigh[illegible] liness and also occasionally to actual cannibalism

De-beaking or the use of spectacles will prevent many cases of feather pecking or cannibalism.

6. **"Breeders'" Rations** (mashes or pellets) are compounded with a view to supplying the requirements of birds whose eggs are going to be incubated. They supply additional vitamins and minerals which pass over to the day-old chick *via* the yolk sac. If an ordinary layer's ration is used instead, hatchability will fall and an increased number of "dead-in-shell" may show characteristic defects.

7. **Ducks, Turkeys, and Pheasants.** Ducklings thrive equally well on chick pellets, but special "starter" rations are now being marketed for turkey poults and pheasant chicks. In both cases the protein and vitamin levels are much higher than those intended for chickens and ducklings. "Pre-starter" rations for turkey poults are also available (0–3 weeks of age). Dilution of these feeds with grain is to be avoided.

8. **Antibiotic Feed Supplements.**—Procaine Penicillin, Aureomycin, and Terramycin are the three antibiotics used as feed supplements for poultry in this country. At *low* levels (5–10 gm. per ton) they overcome sub-clinical diseases due to intestinal bacteria, etc., and as such are used to stimulate the growth of table chickens and also to improve their feed conversion. At *high* levels (50–100 gm. per ton) antibiotics may be used to overcome various stress factors (*e.g.*, chilling), as well as certain maladies, such as Pullet and Round Heart Disease. They are also sometimes used to boost egg production, and to improve hatchability, but this takes place only if the depression is due to the presence of pathogenic organisms which are capable of being killed off, directly or indirectly, by antibiotics.

No harm can follow the giving of antibiotic feed supplements to poultry; nor is there any risk to humans from such practices, but they are expensive supplements to be used cautiously.

9. **Grit.**—There are two types of grit. (i) *Insoluble*—flint, granite, gravel, etc.—required by poultry of all ages, at approximately monthly intervals, if they are being given grain, grass, or other feeds which require grinding in the gizzard. (Mashes, crumbs, and pellets break down in the gizzard satisfactorily without grit.) An excess of grit may pass through the gizzard to cause irritation of the intestines. (ii) *Soluble*—limestone, oyster, etc.—required by layers daily, unless a completely balanced ration is being used. Chick rations usually require none.

Digestion in the Hen.

Unlike most farm animals, poultry swallow their food whole. It passes through the crop and preventriculus (stomach) to the gizzard, where it undergoes slow disintegration under the powerful contractions of its dark-red muscles coupled with the presence of hard, flint-like pieces of grit or stone. As soon as the gizzard is full all succeeding feed is stored in the crop—at the base of the neck—where it is warmed, softened, and acidified by lactic and other acids formed as a result of bacterial fermentation. The semi-fluid foodstuffs passing from the gizzard to the small intestines are part digested, but intestinal juices and those from the pancreas complete this process prior to its assimilation and transformation into meat and eggs. (Bile assists the emulsification of the intestinal contents, but does not supply any digestive ferments.) The semi-fibrous residues which remain pass quickly through the succeeding portions of the digestive tract and leave the body later as droppings—tinged with a whitish "cap" so well known to the poultryman. This latter consists of compounds of uric acid which are being continuously excreted *via* the kidneys.

A hen passes eight to ten lots of fæces each day, one such mass coming chiefly from the blind guts. It is bright in colour, usually yellowish-brown tinged, and of a semi-liquid consistency. It is free from fibrous material, but very evil smelling, and sometimes it contains a number of small Heterakis worms ($\frac{1}{4}''$–$\frac{1}{2}''$ long).

Feeding Poultry on the General Farm.

Chicks.—It is vital to give chicks the best possible start in life, and this means using a special chick ration from day-old. The nutritional requirements of chicks are complex, but their actual food *consumption* is low and, therefore, for both these reasons it is a really sound plan to use a well-balanced chick feed containing animal and vegetable proteins, vitamins A, B_2, D_3, and E. Since chicks eat only 5–6 lb. of feed up to 8 weeks the cost of feeding a special, balanced Baby Chick ration is only about 2*s*.

Do not try to economise by using home-grown grains at this period, because they are somewhat unbalanced and better reserved for the later growing stages. In other words, feed a balanced chick ration as long as possible, and do not dilute it even with skimmed milk, because this upsets the balance of the other ingredients.

Growers.—As a contrast, growing stock aged six to twenty weeks can be given a more bulky ration, and grain can then be used freely, also household scraps, minced vegetables, etc. Wheat is the best grain, but oats or barley are also quite satisfactory. If dried grass or clovermeal is available 5 per cent. can be added to the ration, providing it is of good colour and quality.

As regards special foods a Grower's pellet or mash is best if little grain is available, but if there is plenty, then a "Grain Balancer" ration is better. Broadly speaking, one should give 1 part of grain balancer mash or pellets to 2 parts of grain in the early stages, then half and half when the birds are about four months old, and at point-of-lay pullets should be given three parts of grain balancer to two parts of grain.

Laying-Stock.—The feeding of layers is simple, but the ration must be balanced for economic egg production. It is important that a layer receives 4–5 oz. dry matter containing not less than 15–16 per cent. of good-quality protein. This can be given in the form of pellets or mash; generally provided *ad lib.*, but a 2-oz. feed of wet mash is popular for breeding stock. For hen batteries the ideal ration consists of 4–6 oz. of hen battery pellets.

Special high-energy layers' feeds are prepared for use in cold weather by heavy breed pullets, 3–4 oz. being eaten daily.

Table Poultry.—Special rations are now also available for table poultry production. They contain added proteins and vitamins and special growth factors such as antibiotics like *penicillin*; also anti-coccidiosis agents like the "sulpha" or "nitro" drugs; they are higher in energy and lower in fibre than ordinary chick rations, and as such have a better feed conversion. "Broiler Starter" crumbs are fed during the first 6 weeks, then "Finisher" or "Fattener" pellets.

Breeding Stock.—The feed for breeding stock must support the bird for its maintenance and egg-production requirements, and it must also supply nourishment for the resultant day-old chick. This can be supplied by 4–5 oz. breeders' pellets (or mash) plus 1 oz. grain. Such feeds should commence 3–4 weeks before the hatching season starts. For those poultry breeders keeping their stock intensively (on the deep-litter system) it is advisable to omit the grain, and to feed a "Poultry Breeders" ration exclusively. Fresh greenfood is not essential.

EGG PRODUCTION.

Most domestic hens of the improved breeds—R.I.R., Lt. Sx., W.W., Buff Rock, Leghorns, etc.—are capable of laying 180–220 eggs per bird during their pullet year, provided they receive a balanced diet and are managed with common sense. As a fact, many families have been bred to lay from 240 to 250 eggs per year, and just as there are a few cows which can be expected to give 3000 gallons of milk, so there are occasional pullets which lay over 300 eggs in a year.

Laying stock should receive as few checks as possible during their rearing stages, which implies that they will have remained free from B.W.D., Coccidiosis, etc., and that they will have received a good, generous diet and will not have been unduly exposed to severe climatic conditions.

Chicks hatched in the spring of the year start laying about twenty to twenty-six weeks later, the light breeds laying earlier than "heavies" by about two to four weeks. The ovary starts to develop actively about one month before production commences, and the associated oviduct

becomes equally active, increasing in both length and diameter. Both these functions are governed to a large extent by hormones, formed by certain small glands, *e.g.*, the pituitary gland at the base of the brain, the thyroid gland, etc. In this connection light plays an essential part.

There are no obvious signs that laying is a painful process, but in a few instances slight cloacal hæmorrhage occurs at the time the first egg is laid, and sometimes this is known to coincide with the passage of a much larger egg than normal. The first twelve to twenty-four eggs are generally the smallest, weighing on the average about 1¾ oz., but once maturity is reached, egg size remains relatively constant, averaging 2–2¼ oz. in most cases. But even larger egg strains of poultry have been developed, by selective breeding, and in such cases their eggs will weigh 2¼ oz. and over. The production of very large eggs is to be discouraged because they are uneconomic to produce.

Egg size tends to fall in the hotter, summer months when day temperatures exceed 85° F., and shell texture also deteriorates.

When pullets first come into production not infrequently they lay soft-shelled or double-yolked eggs, but neither should be considered seriously, as in most cases normal eggs quickly follow.

Double-yolked Eggs.—Should the ovary release two yolks simultaneously or separated by only a very short interval, this will result in the formation of a double-yolked egg; whereas if the yolks are liberated at an interval of several hours, two eggs are likely to be laid during the succeeding twenty-four hours.

Cracked and Soft-shelled Eggs.—Cracked eggs may result from: (i) a defective diet, the rations being defective in calcium (lime), phosphorus, or vitamin D_3; (ii) a weakness of the oviduct; or (iii) local damage, as from the use of a faulty nest-box or badly constructed hen-battery cage.

When soft-shelled eggs appear, the "egg" being expulsed before the shell has had time to be laid, this may be a temporary defect due to faulty nutrition or disease such as Fowl Pest. Isolated cases should be ignored.

Mis-shapen Eggs.—These are proof that the oviduct is functioning peculiarly, and in a few cases they are associated with the presence of a tumour or other obstruction involving a ligament of the oviduct. Therefore the repeated laying of such eggs indicates that such a bird should be removed from the flock.

Annual Production.—Egg production falls as a bird gets older, and the following figures give an indication as to what may be expected from hens as they get older:—

Pullet Year	200
Second Year . . .	160
Third Year	125
Fourth Year . . .	100

Composition of Eggs.—The increase in albumin which occurs in large eggs can be seen from the following tables:—

Egg Size.	*Albumin.*	*Yolk.*	*Shell.*
1¾ oz.	57%	32%	11%
2¼ oz.	62%	27%	11%

The colour of the yolk is dependent almost entirely upon the diet, and if the latter is devoid of greenfood and maize the resultant yolks will be almost white. In general, the more greenfood the deeper the yellow-golden colour, but in some cases believed to be due to certain weeds, reddish orange colours may occur. Green yolks may be due to feeding an excess of acorns or using certain samples of cottonseed meal, or from too much herbage.

Value of Daylight for Egg Production.—Farmers do not always appreciate that there is a minimum amount of daylight required by Nature as her normal stimulus to egg production. Experiments at Stoke Mandeville have shown that where daylight is restricted, as by the absence of suitable windows or roof-lights, such pullets will each lay sixteen eggs less during the winter months compared with sister pullets kept in hen-battery cages facing good daylight. Light is the stimulus to ovarian activity, not heat or humidity. It can be from the sun, electricity, gas, or paraffin. Its intensity is important.

Value of Night Lighting.—In the autumn when the hours of daylight are decreasing, egg production can be stimulated if electric or other artificial lighting is used to extend the period of daylight to about fourteen hours. Using 60-watt lamps placed one per 200 sq. ft. of floor space, suspended about 6 ft. above the floor, the right intensity will be achieved. Fluorescent lights are not superior to incandescent lighting. Experiments have shown that the use of 1500-watt lamps for 20 seconds 3–4 times during the night also acts as an efficient stimulus to the ovary—the light effect being *via* the eyes and pituitary gland at the base of the brain. This is known as "flash" lighting.

Controlled Environments.—Experiments have confirmed that pullets given twelve hours of light and a constant temperature of 65° F. laid twenty-four eggs more in the year (forty-eight weeks) than comparable stock housed on deep litter but receiving no artificial light or heat. But pullets from the same batch given twelve hours of light but no artificial heat laid twenty-two eggs more than their controls. Thus the essential factor in increasing winter egg production is light (2–3 ft.-candles) and not heat.

TABLE BIRD PRODUCTION.

Poultry for human consumption readily fall into several classes:—

(i) **Poussin** (weighing 1¼–1½ lb.) are required for the hotel trade. Double-poussins weigh 2 lb.

(ii) **Broilers.**—Broilers are young chickens aged 9–10 weeks, of either sex, weighing about 3–3½ lb. at killing time. They are now being mass produced by the million, this system of production having recently been introduced into this country from the U.S.A., where over 1700 million broilers were reared in 1958. A suitable standard to aim for to day is 3½ lb. bodyweight, in 10 weeks, with a feed conversion of 2·5 : 1.

Broilers sell at about 8*s*. to 13*s*. apiece to housewives, and are available throughout the year.

(iii) **Roasters** (weighing 4–6 lb.), for both the housewife and restaurant trade, can be carved into four or six portions. They are aged ten to sixteen weeks, and will reach the required weight all the more quickly if they receive special "Table Poultry" rations throughout.

Heavy-weight roasters of 7 lb. or more are also available, usually as *Capons*, but they are less economic to produce. They are most popular at Easter and Christmas. The heaviest are obtained by caponisation—surgically or chemically—and are aged from fourteen to twenty-six weeks.

Capons are male birds deprived of their testes in order that they may fatten quickly. The operation is carried out at about eight weeks of age, but "slips" occur, and a few cockerels may even die. Six months later such capons will weigh 2–3 lb. heavier than ordinary cockerels, *i.e.*, about 9–12 lb. apiece.

Chemical Caponisation by means of implants (15-mg.) of female sex hormones (stilbœstrol, hexœstrol, etc.) is rapidly becoming popular, because it is cheaply and easily carried out, causes no deaths, few slips, and the results are positive in 4–5 weeks' time, when the injected birds will be considerably fatter than normal. Such birds stop crowing, go pale in the comb, and lose their combative instincts. Internally there are heavy deposits of fat lining the abdomen and also between the muscle fibres. Older cocks aged one to three years can be tenderised by being given two such implants at six-week intervals, the first to be given three months before killing.

A new method for the chemical caponisation of poultry is to inject the drug in paste-form so that after injection it is all absorbed, because pellet implants sometimes remain only partly absorbed. Another method is to give the drug in the feed, in which case *dienœstrol diacetate* is used, and not stilbœstrol. Although less body fat is deposited internally with this method, it might become popular because of the ease of administration.

Chemically Caponised Turkeys.—Female turkeys respond very well to chemical caponisation, and should be implanted with two 15-mg. Hexœstrol

tablets three or four weeks before killing. Stags however, are less reliable, and require 30 mg. six weeks before and a further 30 mg. three weeks before killing; even so, the results are doubtful. For turkeys being killed off at 16 weeks caponisation 1 × 15 mg. tablet should be used in conjunction with a high-energy ration.

(iv) **Boiling Fowl** are of two classes: (*a*) specially, fat, tender, yearling pullets (5–7 lb.), taken direct from hen batteries, where their special environment will have meant that they will not have been subjected to exercise (which toughens the meat). A premium of about 2*d*.–4*d*. per lb. can usually be obtained in favour of such birds at the end of their first laying season. (*b*) Hens of all other classes and ages—these are less tender and, if taken from free range, are usually lighter (3¾–5½ lb.).

(v) **Ducklings** for roasting purposes are young, succulent, and tender, and weigh from 4½–8 lb. at 8–8½ weeks of age. Older ducks are seldom profitable unless special circumstances demand their retention to about 15 weeks of age.

(vi) **Turkeys** for roasting at home vary in weight from 6–20 lb.; the females weighing about two-thirds that of the male. Older birds are only of use to the hotel trade. The world's heaviest turkey weighed 65 lb.

(vii) **Geese**, like turkeys, are mainly fattened for the restaurant trade, and weigh at nine months 10–20 lb., but their popularity is not increasing in spite of the fact that they eat large quantities of grass and very little "concentrates."

BRITAIN'S BROILER INDUSTRY.

The development of a broiler industry in Britain is a recent innovation, for whereas none were sold in 1953, last year (1959) about 90 millions were marketed. This is the result of specialisation—hatcheries producing special chicks, which grow quickly, feather rapidly, and are mainly white skinned. They are reared in intensive houses which have certain unusual features, allowing 0·7–1·0 sq. ft. per bird. They are 30–40 ft. wide, insulated, and often ventilated by electric fans. Broiler houses hold 5,000–10,000 birds and the aim is to get them weighing about 3½ lb. at 10 weeks. Large packing stations, capable of plucking and eviscerating thousands of broilers daily, have been built, often in conjunction with organised "broiler groups". These are co-ordinated units designed for the economic production and marketing of broilers at a profit. Broilers are sold whole (eviscerated), or in parts—breasts, half chicken, etc. Their present-day retail price ranges from 8*s*. to 13*s*.

DUCKS.

Ducks have many advantages over chicken—they grow faster, weigh heavier, lay more eggs and suffer from fewer diseases; yet they are not as popular as might be expected—why is this?

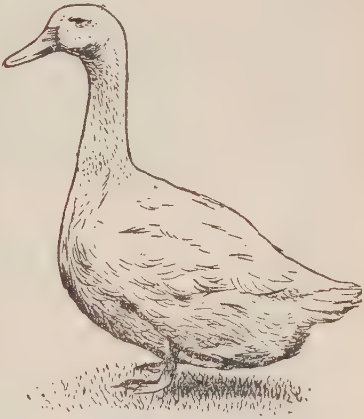
Firstly, they may not make a profit, because there is sometimes a consumer prejudice against eating duck eggs, but like eating pork in a month without the letter "r" in it, this prejudice is more fanciful than real. It arose no doubt because there have been occasional deaths or illnesses due to the consumption of Salmonella-contaminated eggs; but there are also other and more important sources of this type of infection.

Secondly, the egg production of the table breeds of ducklings—as opposed to the layers—is often low, and therefore there is a very seasonal trade in ducklings, except in the case of Penines and Pekins now being hatched the year round.

Breeds.—As layers the Khaki Campbell breed is supreme, many strains laying upwards of 275 to 300 eggs per year. The *Pekin* is an excellent dual-purpose breed, some strains of which are also good layers; and there is also the *Indian Runner*. But for table work the *Aylesbury* is easily the heaviest and most rapidly growing breed in the country, but its poor egg production is against its expansion. The new *White Penine* breed is nearly as good as the Aylesbury for table purposes, and is also an improved layer. Average weights are: Khaki Campbells 4 lb; Indian Runner 4½ lb.; White Penines 5–5½ lb.; Pekins 5¼–5¾ lb.; Aylesburys 5¾–7 lb. at 8–9 weeks.

Rearing.—Ducklings are easy to brood, and where electricity is available infra-red ray lamps are ideal for the purpose. They can be taken off heat at two-and-a-half to three weeks of age—at least one to two weeks earlier than chicken. Although they need plenty of drinking water, a pond or stream is not a necessity, and puddles should always be avoided, as they may harbour disease parasites. Ducklings grow best on pellets or crumbs given from day-old to killing at 8–9 weeks. By four weeks of age ducklings can be given bulky feeds containing steamed potatoes, swill, Tottenham pudding, etc. They will reach their second feathering stage by 9–10 weeks of age, and should be killed off before this period is reached, otherwise stubbing will be difficult. Wet plucking is not satisfactory for ducks, and dry plucking requires to be followed up by careful hand stubbing—but the feathers fetch 7*s*. per pound. (Hen feathers fetch only about 6*d*. per pound.) Alternatively, wax plucking eliminates hand stubbing, but the value of the feathers is lost.

As table ducklings reach 6 lb. by eight to nine weeks of age compared with fourteen to sixteen weeks for cockerels, they should be cheaper to produce, but day-old ducklings at 3*s*. apiece cost three times that of cockerels. In proportion there



AYLESBURY DUCK.

is less meat on a duck, and for these reasons it falls into the luxury class of table poultry.

Diseases.—Ducks do not suffer from Coccidiosis, Gapes, Newcastle Disease, Fowl Pox, or Fowl Paralysis, but they do get Salmonella infections (Keel Disease), virus hepatitis, diseases of the reproductive and excretory systems, and tumours. *S. œrtrycke* infection is responsible for very heavy losses in young ducklings aged three to fifteen days; and survivors may lay contaminated eggs for long periods. Eggs from such birds may be the cause of food poisoning, but it would not occur if attention was given to avoiding the consumption of raw eggs, or of boiling them for ten minutes. This will destroy any Salmonella infection present. (Table ducklings are never the cause of food poisoning in man.) Attention should always be given to collecting duck eggs in as clean a state as possible, and if they are dirty they should be cleaned in hot water (80–90° F.) containing a detergent, *e.g.*, a quarternary ammonium compound; or one such as "Santobrite."

TURKEYS.

Whereas an average fowl will weigh from 5 to 7 lb. at maturity, a turkey hen will weigh more than twice as much; male birds ("stags" or "toms") weighing from 20 to 35 lb. apiece.

These large birds were ideal for family parties

thirty to forty years ago, but with smaller families, and small ovens, the day of the really large turkey has passed, except for the restaurant trade. To-day housewives demand a bird weighing 8–15 lb., which calls for hen turkeys or specially " finished " young males aged 14–18 weeks.

Breeds.—For breeding pens one stag to seven hens is commonly practised. Up to 1950 the most popular turkey in Britain was the *American Mammoth Bronze* (A.M.B.) weighing 14–24 lb. A peculiar sheen to the dark feathers giving the bird its " bronze " character.

Broad Breasted (white and bronze) turkeys carry additional breast meat and weigh 15–30 lb. at five to seven months of age. Of North American origin these are now our most popular turkey.

The *Norfolk Black* is an excellent bird for the general farmer, being lighter than the A.M.B., but with a particularly nice, plump breast.

The *British White Turkey* (also known as the " Austrian White ") is almost as heavy as the A.M.B., but its feathers are more valuable. They are very popular in the south-eastern counties. A smaller white turkey recently imported from America, the *Beltsville Small White*, matures two to four weeks earlier, and weighs about 8–15 lb. Its economical qualities are making it very popular, particularly its good egg production and better hatchability.

The demand for smaller turkeys has led to the production of " Baby " turkeys (" Broilers ") aged twelve to sixteen weeks, weighing 6–10 lb. Any breed can be used, but at this age they lack fat under the skin, unless " finished " with specially prepared rations in conjunction with chemical caponisation, using Vet-jecta paste or pellet implants.

Rearing.—Turkeys are not difficult to rear if given: (i) a correctly balanced diet right from hatching; (ii) plenty of heat under the hover (95° F.); they should be (iii) kept away from all other poultry; and (iv) preferably reared intensively for the first eight weeks.

AMERICAN MAMMOTH BRONZE TURKEY.

The first feed should be placed on a piece of coloured paper laid over the floor under the hover; a scattering of flint grit is also necessary, and the drinking-water must be close at hand. Turkey Starter rations must be kept in front of the poults all day long, and no grain or greenfood should be given for the first eight to ten weeks. By this time they will weigh from 4–6 lb., and their teething troubles will be over, except for diseases such as Blackhead and Coccidiosis. The new drug " Entramin-A " is specific for Blackhead, and Coccidiosis can be controlled by the use of sulpha drugs. A separation of turkey poults from domestic hens commonly avoids serious losses from Worms, Gapes, Fowl Pox, and Blackhead. *See also* Y14.

GEESE.

Few geese are kept commercially, although many farmers keep half a dozen for their own use at Christmas-time. They eat large quantities of grass, and require little extra feeding beyond that which can be supplied by home-grown grains.

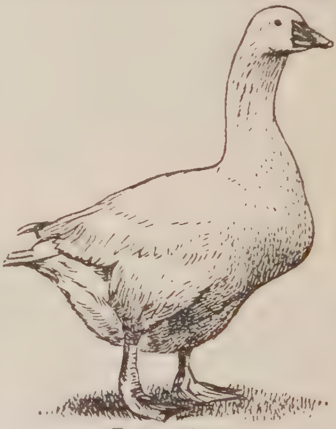
Breeds.—In general, the larger the breed, the smaller the number of eggs laid by the females, thus the Chinese may lay 60 or more eggs, compared with only 20 by the Toulouse. The *Grey and White Chinese* are, however, less popular because, although of attractive external appearance, their flesh is dark, and they are very noisy. Among white-feathered breeds the *Roman* and *Embden* are favoured, as is the grey *Toulouse*; but many farmers prefer a crossbred, *e.g.*, Embden × Toulouse; or Roman × Toulouse. The very rapid growth rate of geese can be seen from the following results at Stoke Mandeville (1954):—

Weeks.	*Chinese.*	*Roman.*
1	8·8 oz.	9·9 oz.
4	3 lb. 1 oz.	4 lb. 5 oz.
8	7 lb. 0 oz.	8 lb. 8 oz.
12	8 lb. 15 oz.	10 lb. 6 oz.
14	9 lb. 6 oz.	11 lb. 12 oz.

Although when mature geese weigh from 15–30 lb., they are much less popular than turkeys, partly because they carry less flesh (on the breast), also because the flavour and colour of the meat is less attractive.

Breeding stock are not chosen until they are 2–3 years old, but they may be used for upwards of 5 years. For light breeds one gander to 4–5 females is practised; for heavy breeds one gander to 2–3 females. Geese often mate for life, and it may be difficult to re-mate them if breeding pens are broken up.

Incubation takes twenty-eight to thirty days, and from ten to twelve eggs may be set under a goose, but an ordinary domestic hen can only take about four—which must be turned daily by hand. They should be sprinkled with warm water during the latter half of the incubation period, because they need more moisture than hen's eggs. Newly hatched goslings can also be brooded rather like



EMBDEN GOOSE.

ducklings, and can be taken off heat at ten days of age. Chick crumbs, freely available with *ad lib.* water, provide their best feed, but by three weeks of age they will be eating grain and grass freely. Rather than give them nothing but grass during the summer months, a small daily feed of " Growers " pellets is recommended. About one month before killing they should be given more pellets, preferably " Poultry Fattener."

Goose feathers are valuable, about 1 lb. being obtained from each mature goose, and they may fetch up to 10*s*. per lb. for the finer types. In Holland geese are plucked twice a year—alive—but this practice is not allowed in this country.

Diseases.—Geese are comparatively disease resistant, and in this country seldom suffer from any epidemics except when they become heavily infested with gizzard worms or coccidia. Goslings require careful management during their first two to three weeks in case of chilling, impactions of the intestines, etc., but from then on they usually make good progress.

POULTRY MORTALITY.

The degree of mortality experienced during the rearing season often gives an indication as to the efficiency of the poultryman and his methods. Providing that there are no actual outbreaks of disease, the following are average figures:—

		Mortality, %.
Chicks	1–8 weeks	5
	9–26 weeks	5
Pullets	6–18 months	10–15
Hens	19–30 months	8–12
Turkeys	1–26 weeks	4–8
Ducks	1–9 weeks	5
Geese	1–4 weeks	2

PREVENTING FEATHER PECKING AND CANNIBALISM.

Apart from attention to management—keeping birds occupied by continuous dry-mash feeding, pecking at greenfood, roots, etc.—there are three main methods used for controlling these vices.

Hen Spectacles.—These are made of plastic or of light-metal alloys and fit snugly over the upper beak so as to cover the eyes in order to interfere with long vision. Thus, a bird fitted with "Dewdrop" spectacles can be expected to see its food but not its neighbours, and therefore Vent Pecking and Cannibalism are prevented.

De-beaking.—De-beaking consists in removing a small portion of the upper beak so that the bird concerned is unable to approximate its two mandibles (upper and lower) accurately. In this way feather pulling is avoided and fighting propensities reduced. It can be carried out at any age, even at day-old, but the younger the bird, the greater the need to carry out de-beaking again in a few weeks' or months' time. The operation can be performed quite successfully by any intelligent poultry farmer who has had the necessary tuition in using a proper de-beaking instrument. This comprises an electrically heated "knife" which cuts through the horny portion of the beak (upper), searing it at the same time, and in this way hæmorrhage is avoided. Day-old broiler chicks are sometimes de-beaked for table-poultry production; laying stock are not generally de-beaked until the time of their entry intc intensive conditions at point-of-lay.

Visors.—Visors made of metal, like hen spectacles, are applied to the bridge of the nose, and are now being popularised for use with turkeys. They are kept in position by means of a split-pin passed through the nostrils. Turkey "*bits*" are equally successful in preventing feather pecking. These consists of a rustless metal ring (incomplete) which lies between the mandibles but above the tongue: its ends are inserted into the nostrils and clipped into position.

Causation.—Boredom combined with bullying, accentuated by intensive conditions of management.

DISEASES OF POULTRY.

It should be remembered that, in the case of some diseases, birds which recover remain as carriers of the causal germs; this applies particularly to B.W.D., Infectious Colds, and certain Salmonella infections. For this reason alone it is wise to purchase all one's stock from one source and not go to two or three suppliers, or there will be two or three chances of introducing infection on to one's premises.

When any birds die they should either be incinerated or buried deeply in lime, but in the case of commercial poultry farmers it is a good plan to have such birds examined *post-mortem* by a veterinary surgeon or some other competent person, who will be able to state from what the bird has died and what steps to take in order to prevent other poultry from catching the same complaint.

Quarantine.—Whenever birds are purchased or brought back from Laying Trials, Shows, etc., it is a good plan to keep them isolated in quarantine for three or four weeks, during which time if they are going to suffer from any infectious disease it should show itself.

Disinfection.—Before attempting to rear chicks always make certain that the brooder house and equipment are thoroughly disinfected. Food and water troughs, hovers, etc., should be scraped and soaked in hot, strong, soda water (½ lb. to a gallon); immersed in a disinfectant (Jeyes Fluid 1 : 100), and finally rinsed in clean, cold water. In this way disease germs and viruses will be destroyed and the equipment rendered quite suitable for future use. In the case of incubators and large intensive or broiler houses fumigation with formaldehyde or sulphur is recommended.

COMMON POULTRY AILMENTS.

Aspergillosis, due to a fungus, causes respiratory symptoms in all species of poultry with gasping as the most prominent symptom; mortality is high. The lungs and air sacs show multiple pale nodules. There is no treatment. Avoid musty hay in chick-boxes; mouldy straw bedding, etc. Sterilise feed and water containers daily. *This disease can be transmitted to man.*

B.W.D. (Pullorum Disease), due to a specific germ, attacks chicks and poults during the first few days after hatching, and mortality is high. White diarrhœa may be evident. The new drug *Furazolidone* ("Neftin") is valuable for treating B.W.D. in chicks and even for eliminating a high percentage of "carriers." B.W.D. is egg transmitted, and all breeding stock should be blood tested each season before use. When hens die from this disease they show degenerate, nodular ovaries from which can be cultivated the causal germ *S. Pullorum.*

Big Liver Disease (Lymphomatosis) is a form of Fowl Paralysis, the liver appearing four to five times as large as normal; the spleen is often enlarged too. Affected pullets often show a scanty, green diarrhœa a short time before death. Believed to be caused by a virus, there is no cure or treatment for Big Liver Disease.

Bumblefoot represents a local infection of the ball of the foot. Usually only one foot is involved, and the site of entrance of the pus-forming bacteria is seen easily. Occasionally the trouble is tuberculous, but more frequently it is due to *cocci* which penetrate to the region of the tendons below the foot, where the pus which they form shows as a marked swelling. Surgical treatment is often successful.

Cloacitis (Vent Gleet) is an inflammation of the vent, commonly seen in pullets; its origin is not clear, but it is certainly not the venereal disease believed in by many farmers. Some cases respond to local treatment, but in many others a stench develops which indicates clearly the unsuccessful nature of the treatment, and such cases are better killed.

Coccidiosis is a specific disease of the intestines affecting chickens, broilers, turkeys, and occasionally ducks and geese. There are two main forms: (i) cæcal, and (ii) intestinal. Both are caused by microscopic parasites—coccidia—whose life cycle takes place in the mucous membrane lining the gut. Affected birds appear listless, ruffled in the feathers, and many die. Acute Cæcal Coccidiosis is characterised by bloody droppings; in the intestinal form diarrhœa may be prominent. In geese the kidneys are frequently attacked. *Treatment* using sulpha drugs is highly effective. Sulphamezathine (I.C.I.), and Embazin (M. & B.) can be given in the feed or water. Each coccidium gives rise to its own immunity, so that a chick having suffered from Cæcal Coccidiosis may be attacked later by one of the other intestinal forms of Coccidiosis. The sulpha drugs mentioned cure the disease and also allow immunity to be developed at the same time.

Coccidiosis Prevention.—Apart from good management practices, the prevention of many outbreaks of coccidiosis is by the inclusion of certain drugs in the feed *continuously at low levels*, *e.g.*, Arzene, Bifuran, Glycamide, Nicarbazin, Nitrofurazone, Nitrophenide, Sulphaquinoxaline, Trithiadol, or Zoalene. These, however, can only neutralise a given number of coccidia, hence the importance of a careful check on feed intake.

Damp litter should be avoided, and ample feed trough space provided or the birds may not eat enough medicated feed to prevent coccidiosis.

Colds may either affect isolated birds or be of a highly infectious nature. Sneezing, coughing, gasping, and a swelling of the face and wattles appear in this disease, which is commonest in growing stock. Sulphathiazole (M. & B. 760) and allied drugs are specific for certain types of infectious colds, and should be given at the earliest opportunity. Persistent cases and those due to pleuro-pneumonia-like organisms (P.P.L.O.) as in Chronic Respiratory Disease (C.R.D.) require to be treated with streptomycin (0·2 gm.), for which a veterinary prescription is required. Mortality is not high, but severe culling is necessary.

Crooked Breastbones occur in young stock receiving improper feeds lacking calcium, vitamin D, etc. Some strains and breeds are more susceptible than others.

Crop Binding is a stoppage of the crop, generally through eating long grass, straw, etc. It never occurs in hen batteries, seldom on deep litter, but be seen in hen yards, and is commonest in birds kept on free range. Good management will avoid most cases, the remainder require surgical treatment.

Diphtheria (*see* **Fowl Pox**).

Dropsy is characterised by an accumulation of fluid in the abdomen. It is often secondary to cancer of the intestines. There is no cure or prevention, and affected stock should be killed and buried or incinerated.

Egg Binding implies an impaction of the oviduct either by yolks or shell-less eggs, etc., or it may refer to cases where a fully shelled egg has failed to be extruded at laying time. The former cases are without treatment, but the latter can be removed by manipulation. Only isolated cases occur, and their prevention is not easy.

Fowl Cholera is a specific disease due to a germ —*P. avicida*—affecting all species of poultry and having a high death-rate. Sometimes there is a swelling of the wattles with local abscess formation. Affected stock suddenly become ill, the birds are dejected, and a number will die overnight. Broad spectrum antibiotics (aureomycin and terramycin) reduce the mortality, but "carriers" may remain.

Fowl Paralysis.—The Fowl Paralysis "complex" comprises cases of leg, wing, neck, and eye paralysis, all due to an infiltration of the parts by an accumulation of abnormal cells. A second form of the disease, characterised by tumour formation, is known as Lymphomatosis, and included in this group is "Big Liver Disease." These diseases, collectively termed the "Avian Leucosis Complex," are all believed to be due to viruses, but there is no cure or any medicinal treatment of value. Many of them are of an infectious nature, spreading amongst young stock during the first few weeks after hatching, but a few cases may be egg transmitted.

The domestic fowl is chiefly affected, frequently pullets at point-of-lay; turkeys are but rarely involved, whilst ducks and geese never suffer from Fowl Paralysis. Some families and breeds are more resistant or susceptible than others, and pedigree breeders are now trying to establish Fowl Paralysis resistant strains. *To minimise the introduction of these diseases, purchase all replacement stock from one source only at day-old.* Rear them as far apart as possible from all other poultry, especially adult layers and manure heaps. Keep them so isolated for as long as practical, certainly 12–16 weeks.

Fowl Pox is due to a virus, and is characterised by wart-like or cheesy growths on the comb, eyelid, face, and wattles. Chicken, turkeys, pigeons, and canaries can all suffer from pox; ducks and geese appear immune. When the mouth or throat are involved the disease is termed *Avian Diphtheria*

Prevention is by the use of vaccines—*Pigeon* Pox Vaccine giving a shorter period of immunity than that following the use of *Fowl* Pox Vaccine. Immunity is established in fourteen days.

Fowl Typhoid is caused by a germ—*S. gallinarum* (closely allied to that of B.W.D.)—and gives rise to symptoms and losses easily to be confused with those of Fowl Cholera, hence the need for expert advice. *Treatment* (curative)—Furazolidone 0·04% for 10 days in the feed. For preventive purposes use 0·01% continuously. New vaccines prepared at Houghton Grange appear valuable.

Gapes is a disease of young chicks aged less than eight weeks, and also of turkeys. Gapeworms cause irritation, gasping, and suffocation. Barium antimonyl tartrate is the best treatment used as an inhalant (powder).

Infectious Bronchitis caused by a virus is becoming important amongst broilers. A respiratory disorder primarily, affected laying stock lay soft-shelled eggs.

Infectious Laryngo Tracheitis (I.L.T.) is a specific, highly infectious, fatal disease affecting fowls. The causal virus first induces "colds," gasping, and the *coughing up of blood*; but numerous deaths follow. Recovered birds are often carriers. There is no treatment. Vaccines are being tried out.

Infectious Synovitis affects broilers aged 6–[illegible] weeks. It is characterised by swollen joints and breast blisters. Aureomycin is the best treatment.

Leg Weakness is a symptom and not a disease. It may be seen in Rickets (chicks); Fowl Paralysis; Layer's Cramp (hens); worms and Coccidiosis; dietetic errors, etc.

Lice (*see* **Parasites**).

Liver Disease is a term used to indicate those diseases characterised by a gross deformity of the liver, *e.g.*, Tuberculosis, Lymphomatosis, internal hæmorrhage from rupture, etc.

Marble Bone Disease affects chickens, revealing enlarged thickened bones, especially in the legs and wings. It is incurable, and there is probably a genetic aspect to the problem, also a virus.

Newcastle Disease (Fowl Pest) is a notifiable disease causing serious losses to the industry, with respiratory and nervous symptoms, nasal discharges, diarrhœa, gasping, twitching, paralysis, and death. One form in adult birds shows only as an infectious type of mild cold (without serious losses)—egg production falls dramatically. There is no cure. Report all suspect cases to the police immediately. Vaccines are being used successfully for preventing this disease in the U.S.A., India, Palestine, etc.

Parasites are divided into: (i) external and (ii) internal. The former comprise lice and mites (common) and fleas (uncommon). Some harm may be caused by their irritation. They can be controlled by the use of D.D.T. (lice), and "Lorexane", nicotine sulphate "Malamite", etc. for mites.

Internal parasites consist of coccidia (*see* Coccidiosis) and worms. The Large Round Worm (Ascaridia) may do harm, but the common cæca worm (½ in. long) rarely causes any trouble; hair-worms in the crop, gizzard, and small intestines are also important. Tapeworms require the presence of an intermediate host (slug, snail, etc.) and may be a serious cause of loss. Flukes are rare, but *Acuaria* may be found in waterfowl.

A new drug Piperazine, given in the feed or water, removes large round worms (Ascaridia) successfully; phenothiazine is used for cæca worms, and tetrachlorethylene for gizzard worm infestations.

Peritonitis refers to an inflammation of the membrane (peritoneum) which lines the abdominal cavity. The commonest form affects laying stock and follows an infection (ascending) of the oviduct. It is seen, too, in certain cases of blood poisoning and also following perforation of the gizzard or intestines. It is usually fatal and not detected before death.

Pneumonia is common as a terminal feature to congestion of the lungs following chilling. It is seen also in Aspergillosis in chicks (Brooder Pneumonia) and B.W.D.; antibiotics (*e.g.*, penicillin) or sulpha drugs can be used for valuable poultry suffering from pneumonia.

Prolapse of the intestines or oviduct results from an eversion of the cloaca and associated parts. The cause varies, but may be of digestive or reproductive origin. Some cases can be corrected if caught early, the parts being anointed and replaced; preferably being held in position for twenty-four hours by a suture. Feed sparingly for two to three days in a darkened room.

Tuberculosis is a specific disease of germ origin, fortunately rapidly becoming eliminated nowadays by the adoption of modern housing practices. It is never seen in young stock, but chiefly affects hens, which lose condition and die. Post-mortem findings are typical, revealing nodules in the liver, spleen, intestines, lungs, bone marrow, etc. There is no curative treatment, but many infected birds can be detected by a blood test (Tuberculin Test).

Tumours are growths of a cancerous nature. They are commonly found in pullets, involving the ovary, lungs, liver, intestines, and kidneys. Some are due to a virus; many show a familial tendency. Very few are capable of being treated, but *Blood Blisters* may respond to cautery, using a caustic pencil or a piece of bluestone rubbed well into the cutaneous cyst.

Vitamin and Mineral Deficiencies are less common to-day, due to the use of specially compounded poultry feeds which include synthetic vitamins A, B_2, D_3, E, K, B_{12}, choline, etc. Cases of Rickets, Curled Toe Paralysis, Dermatitis, and Nutritional Roup are, therefore, becoming rare, and "Slipped hock disease"—of manganese deficiency origin—is often recognised early and treated successfully The ratio between the calcium and phosphorus contents of the diet are important, otherwise leg and bone weaknesses may result.

CULLING POULTRY.

The object of "culling" poultry is to find those which are not paying their way—the duds, the "passengers"—those birds eating a full ration but giving nothing in return.

Culling should be a continuous process, right from hatching time, for there is obviously no sense in keeping even day-old chicks if they are going to be unproductive.

Culling can be considered as both an art and a science, and can be applied for either (*a*) general health, or (*b*) egg production.

Handling Poultry.

Before any accurate examination of birds is possible it is necessary to know how to handle them—how to pick them up so that they remain quiet, as well as the method by which each part is examined in turn. If the poultryman's hand is placed below the bird's breast (with its head turned towards the operator) with the fingers separated so that the little finger and thumb are controlling the bird's two hocks this will be found useful. The other hand is then free to raise the bird's head, to palpate the abdomen or move the feet, etc.

Health and Disease.

The following culling points are important:—

Comb covered by scabs occurs in Fowl Pox.

Eyes loose their colour in Iritis and blindness. The pupil may be "split" or even paralysed.

Face is covered by whitish, powdery scales in Favus.

Nostrils show thick mucus in "Colds."

Mouth contains yellow growths in canker ("Diphtheria") and following injury.

Wattles swell due to the presence of pus, and also in some cases of Fowl Cholera and Coryza.

Wings should be examined for loss of feathers in moulting, bruising, fractures, etc.

Skin shows the presence of blood blisters, wounds, etc.

Breast may be crooked, or affected by a blister, (cyst). *See also* **Infectious Synovitis.**

Vent reveals cases of prolapse, and in Vent Gleet it has a nasty smelling discharge. The vent fluff reveals the presence of lice or their eggs and mites, also diarrhœa and nephritis.

Shanks indicate age, and also the presence of Scaly Leg, and Marble Bone Disease.

Toes may be crooked, twisted or curled.

Toe Nails are short in birds from range (due to scratching) and long in birds from hen batteries.

Foot may be swollen due to Bumblefoot.

Back may reveal impaction of the preen gland at the root of the tail.

Abdomen may be swollen due to tumours, to impacted egg material, liver enlargements, or sometimes full of fluid (dropsy), etc.

Egg Production.

Pullets in production usually show combinations of the following points:—

Head.—Comb large and full blooded, silky Wattles close set—if widely separated this indicates the beefy type, and is due to fat beneath the skin. The eye is set high up in the skull, is prominent and visible from both the front and back of the head. The eyebrow is not overhanging, and the eye fills the socket. The neck is swan-like.

Abdomen shows four fingers' width between the point of the breastbone and the pelvic bones.

Pelvic bones are separated by three fingers' width when most birds are in lay.

In the case of birds out-of-lay the pelvic bones contract, and the breastbone more nearly approaches the vent.

PIGEONS.

Large numbers of pigeons are kept in this country as a hobby, and only a few are reared as table birds. Pigeon racing is a popular sport, but during war or emergency periods they are also used for message carrying, postal services, etc.

Although pigeons belong to the Order *Galliformes*, they are in a different sub-order from that of poultry, and *Columba livia*, the Asiatic Grey Rock Dove, is believed to be one of their main ancestors.

In all their are upwards of 200 breeds of pigeons, but of these the Fantails, Tumblers, and Pouters always attract most attention. The larger breeds for table purposes are Mondains, Runts, Dragoons, and various crossbreds.

Foods and Feeding.—A pigeon's diet should be mixed and consist of seeds, grains, greenfood, and grit. The chief foods used are: peas, especially Tasmanian maple peas; Tick beans; tares (vetches); millet; canary seed; lentils; linseed; and corn of all varieties. When no greenfood or maize is available, and during the winter months particularly, vitamins A and D should be supplied in synthetic form or alternatively as cod-liver oil. Short-beaked breeds are best given small or cracked peas, tares, canary seed, etc. Regular supplies of gravel, granite, or flint grit are necessary, as well as limestone grit, especially during the egg-laying season.

It is fallacious to supply pigeons with flowers of sulphur in the belief that this provides sulphur for the growth of feathers; nor is it necessary to give beans for supplying silica or oyster-shell for iodine. Charcoal is another unnecessary ingredient for pigeons.

The average pigeon eats about 1½–2 oz. of grain daily, the lesser quantity being given to racing pigeons, but during the brooding season a much larger appetite is to be expected when pigeon "milk" is being formed in the crop.

Breeding and Rearing.—Pigeons will breed in any month of the year, but mating naturally takes place in late February or March, and continues to August or September. A second clutch of eggs is often laid before the first brood is fully fledged. The average hen lays seven to eight days after mating—never earlier than the fifth day. Gliding is often a sign of courtship. The hen may sit on the nest three to four days before laying her first egg in the afternoon; the second egg follows about thirty-six hours later. The hen usually sits on them during the night-time, whilst the cock incubates them during the day. The incubation period is seventeen to eighteen days. For normal purposes pigeons can rear half a dozen broods each year, but in order to conserve their energy only one or two should be taken from racing pigeons; it is then also recommended that only one squab per brood is reared. Squabs usually hatch in the morning, never after 3 p.m.

The parent birds brood their young for a full week after hatching, thereafter they may be left uncovered without harm. It is during this first week that identification rings must be put on to the legs of young pigeons. By the end of the second week the young birds will leave their nest; during the whole of this time they live on food regurgitated from the parent's crop. This food is called "*Pigeon's Milk*"; it is the direct result of a hormone (produced by the brain), and is caused by an overgrowth of the lining membrane of the crop which sheds itself as "milk." It is a highly digestible, whitish, semi-solid, granular product passed direct (from either parent) to the mouth of the young squab. It is not a glandular secretion, and to the naked eye looks rather like soaked groats. Early during the brooding period the parent birds "vomit" part-digested grain to their offspring as well as "milk." Foster mothers may be required for Croppers, Pouters, and Short Faced Tumblers, etc. Weaning takes place after three to four weeks, in fact, as soon as the squabs can feed themselves and become independent of their parents. The growth rate and physical development of the young pigeon is quite dramatic from day-old onwards. It is then only covered by brightish yellow, hair-like down, and its skin is devoid of pigment matter. It is extremely weak at this stage, and its eyelids may remain closed for four to five days. By the end of the first week, however, its pigmented quills give it a porcupine-like appearance, and by fifteen days of age the whole bird is covered with feathers. For all practical purposes pigeons are mature by twenty-six days of age, being alert, fully feathered, and typical of the species.

An area devoid of feathers circumscribing the eyelids is known as the "cere"; some breeders pay great attention to this character, but it is really unimportant physiologically. The breast muscles are strongly developed and of deep red colour in contrast with those of poultry. The lining, horny membrane of the gizzard is often coloured green, due to bile; it should always contain insoluble grit for grinding the food. No gall bladder is present, and the cæcal tubes are diminutive. The small intestines are coiled in a spiral fashion. During the mating season the ovary will show only two well-developed egg yolks which, with the large oviduct, occupies almost half the abdominal cavity. Compared with other birds, the heart and lungs are large, especially in racing pigeons. The body temperature registers 107° F. Moulting usually begins in April or May, and it is at this time that the primary flight feathers are lost.

Aviaries and Lofts.—It is usual to build a special pigeon cote for their sleeping, feeding and breeding activities. Such lofts should be white-washed twice a year, and if D.D.T. is added it will help to control flies. A wire-mesh aviary attached to the loft for exercising purposes is common, a minimum of 3 sq. ft. of floor space per bird is recommended, and for fifty pigeons 15 ft. × 12 ft. is satisfactory. For the loft floors sand or sawdust make good litter, but it should be raked over and sifted frequently to remove the bulk of the droppings. Most lofts, nest-boxes, and perches are made of wood, and where space is restricted the nest-boxes can be attached to an outside wall with their entrance direct into the loft. A nesting-box of two compartments separated by a low partition allows the cock bird to take charge of the first brood whilst the hen sits on the second lot of eggs. Nest-boxes should be 14 in. × 14 in. × 28 in. If the front of the nest-box is protected by a 3-in. wooden board, hinged at the bottom, this will help to confine the squabs. An alighting board 4 in. wide in front of each nest is valuable.

Racing and Training.—Young pigeons are generally flying quite satisfactorily by their seventh week, and they should soon be given two exercise flights daily until able to fly for three-quarters of an hour. Before training begins, such young birds must be made to get used to their baskets, followed by "trapping" and learning to recognise their owner's particular call. Consistent light training is better than intensive methods, and should begin when the birds are about four months old, and flights should be extended gradually from three miles to 100 miles as progress is made. Quick trapping to avoid loss of time after races is gained by feeding only inside the loft and by calling the birds through the trap by a whistle or other standard noise. Feeding should always be carried out *after* exercising.

Homing.—Many birds, other than pigeons, have homing instincts, and these are not confined to the brooding season. Homing is an inherited quality of uncertain origin which can be developed by selective methods and directional training. It is now generally considered that the primary sense of orientation is not related to visual landmarks, but navigation as such may be related to the position of the sun. Homing is not affected by radar, and although it has been suggested as due to magnetic influences, the use of Faraday cages has disproved this point.

Homing pigeons may fly at heights up to 6,000 ft., but in poor visibility they will come down to within a few feet of the ground. In thick fog they soon appear to lose their sense of direction and descend until the weather improves, but large numbers of birds are lost annually from this and associated causes.

The method of handling a pigeon is important. It should be held in one hand with the thumb across the back, the fingers and the palm of the hand below the abdomen with the first and second fingers lightly gripping the feet.

Diseases of Pigeons.—Diseases of the digestive system account for more losses than any other. Thread-worm infestations (Capillariasis), coccidiosis, and Trichomoniasis are, however, all amenable to treatment using modern drugs. A veterinary surgeon should be consulted regarding the anthelmintics, sulpha, or nitro drugs to be used. For Salmonellosis (Paratyphoid) furazolidone may prove useful. *Salmonella* infections account for a very large number of deaths, especially in young pigeons, one form of the disease being termed "*Paratyphoid.*" Arthritis sometimes occurs in pigeons, and it too may be associated with *Salmonella* infections.

Many young birds suffer from *Coryza* (cold), and fanciers often associate the chronic form of this disease (Roup) with Pox. *Pigeon Pox* affects mainly the head and eyes, but unlike poultry, many cases do not respond to treatment with tincture of iodine or copper sulphate (1 per cent.). Sudden death (Apoplexy) is sometimes seen in pigeons, but the cause is seldom determined: internal hæmorrhage is associated with many cases. Pigeons can be affected by an important virus disease called *Psittacosis*. Although some cases are transmissable to man, fortunately very few pigeon fanciers suffer from this disease, which is characterised by fever, malaise, and an unusual form of pneumonia. *Aspergillosis* may also be contracted by man from infected pigeons.

Lice and feather *mites* are common external parasites of pigeons, but their control is easy, due to the use of specific remedies, *e.g.*, D.D.T.

Domestic Pets

Feeding, management and diseases of

Domestic Pets

By ALASTAIR N. WORDEN, M.A., (Cantab.), F.R.I.C., formerly Milford Research Professor in the University of Wales.

This section attempts to deal not with all the many hundreds of animals that may be kept as pets, but only with those that are best suited to average homes in Great Britain. The maintenance of monkeys, squirrels, bats, mongooses, and snakes, while quite feasible to those with experience and facilities, requires considerable time and—in some instances—expense. Those who contemplate such exotic pets should consult works of reference, study the methods adopted in zoological gardens, and discuss the matter with experts. Even in the case of the more common animals, the information provided in the following pages is to be regarded only as a beginning, to be supplemented so far as possible by practical experience, discussions with more knowledgeable owners, and the study of more detailed writings.

Certain considerations are basic. Never keep a pet unless you are really interested in it and are prepared to give it due—and regular—care and attention. Don't keep a pet you cannot afford to maintain in health and comfort. Scrupulous attention to cleanliness is essential, and wise feeding is one of the most important factors in avoiding illness and loss of condition.

Since the passing of the Veterinary Surgeons Act of 1948 it is illegal for anyone to practise the diagnosis and treatment of animal diseases unless he or she is: (1) a veterinary surgeon; or (2) a person whose name has been placed on the Supplementary Veterinary Register. (Certain employees of Animal Welfare Societies are specially licensed, but it is intended that in future all animal treatment shall be given by or under the direct supervision of members of the veterinary profession.) Not even a pharmacist may attempt to diagnose or treat an animal. Anyone may, of course, render "first aid," and an owner may—at his or her own risk—apply treatment. It is, of course, a wise precaution to seek veterinary advice for any ailing animal, and the sooner it is sought the more likely it is that good results will follow.

BREEDS AND VARIETIES OF DOGS.

Of recent years, dog-breeding and showing have become specialised occupations, which average people cannot be expected to take up without having adequate time or resources at their disposal. Any amateur who wishes to breed for profit from pedigree animals should most certainly seek expert advice before attempting to do so.

Dogs which are intended for show or for pedigree breeding must be registered with the Kennel Club, 84 Piccadilly, London, W.1. The requisite forms and regulations may be obtained on application to the Secretary.

The breeds of dogs recognised for the purpose of separate Registration and Stud Book entries by the Kennel Club are:—

SPORTING BREEDS.

Afghan Hounds
Besenjis
Basset Hounds
Beagles
Bloodhounds
Borzois
Dachshunds
Deerhounds
Elkhounds
Finnish Spitz
Foxhounds
Greyhounds
Harriers
Irish Wolfhounds
Otterhounds
Salukis
Whippets

Gun-dogs.

English Setters
Gordon Setters
Irish Setters
Pointers
Retrievers
Setters (Cross-bred)
Spaniels

Terriers.

Airedale Terriers
Australian Terriers
Bedlington Terriers
Border Terriers
Bull Terriers
Cairn Terriers
Dandie Dinmont Terriers
Fox Terriers
Irish Terriers
Kerry Blue Terriers
Lakeland Terriers
Manchester Terriers
Norwich Terriers
Scottish Terriers
Sealyham Terriers
Skye Terriers
Staffordshire Bull Terriers
Welsh Terriers
West Highland White Terriers

NON-SPORTING BREEDS.

Alsatians (German Shepherd Dogs)
Boston Terriers
Boxers
Bulldogs
Bull-mastiffs
Chow Chows
Collies
Dalmatians
Dobermann Pinschers
French Bulldogs
Great Danes
Keeshonds
Mastiffs
Newfoundlands
Old English Sheepdogs
Poodles
Pyrenean Mountain Dogs
St. Bernards
Samoyeds
Schipperkes
Schnauzers
Miniature Schnauzers
Shetland Sheepdogs
Shih Tzus
Tibetan Terriers
Welsh Corgis (Cardigan)
Welsh Corgis (Pembroke)

Toys.

Black-and-Tan Terriers (Miniature)
Griffons Bruxellois
Italian Greyhounds
Japanese
King Charles Spaniels
Maltese
Papillons
Pekingese
Pomeranians
Pugs
Yorkshire Terriers

A separate register, called the Breed Register, is kept by the Kennel Club for each breed, except in the cases of the following breeds, for which a separate register is kept for each of the varieties of the breed specified.

Dachshunds.

Long-haired
Smooth-haired
Wire-haired
Miniature (Smooth-haired) not exceeding 11 lb. for exhibition).
Miniature (Long-haired) (not exceeding 11 lb. for exhibition.)

Irish Setters.

Red
White and Red (A.O.V.)

Retrievers.

Curly-coated
Flat-coated
Golden
Labrador
Interbred
Crossbred

Collies.

Rough
Smooth

Spaniels.

Clumber
Cocker
Field
Irish Water
Springer, English
Springer, Welsh
Sussex
Interbred
Crossbred

Bull Terriers.

Bull Terriers
Bull Terriers (Miniature).

Fox Terriers.

Smooth
Wire

Poodles.

Not under 15 in.
Miniature, under 15 in.

Toy Spaniels.

Cavalier King Charles Spaniels.
King Charles Spaniels

The Committee of the Kennel Club has decided to classify those breeds which at present have no separate register, but are included under the heading "Any Other Variety." The classification is as follows:—

HOUNDS.

Dachsbracke
Dachshund Miniature (Wire-haired)
Rhodesian Ridgeback Lion Dog

GUN-DOGS.

Chesapeake Bay Retriever
Kleine Munsterlander
Pointer German Short-haired
Pointer German Long-haired
Pointer German Wire-haired
Pointing Griffon Wire-haired
Setter German Long-haired
Weimaraner

TERRIERS.

Soft-coated Wheaten Terrier
Sydney Silkie

NON-SPORTING.

Bearded Collies
Bouvier de Flandres
Groenendael
Hudky
Leonberger
Lhasa Apso
Maremma Italian Sheep-dog
Norwegian Buhund
Polish Sheepdog
Reisenschnauzer
Tibetan Mastiff
Tibetan Spaniel
Volpino
Wolf Spitz

TOYS.

Chihuahua
Penscher Miniature

In the limited space available it is impossible to describe the special characteristics of the different breeds. The breeds recognised in Great Britain are subject to constant review by the Kennel Club, and it is probable that the number will continue to be added to from time to time.

The dog was probably the first animal to be domesticated in the true sense of the word, and the uses to which he has been put by man are almost legion. Throughout the world dogs are employed to help protect herds and flocks, and indeed the dog trained for shepherding plays an integral part in sheep management. The names Foxhound, Deerhound, and Otterhound all indicate the specific uses to which dogs have been put in the Chase. Greyhounds and Whippets are used in coursing, and work singly or in pairs, rather than in packs. As their names indicate, the various Setters and Pointers are employed to indicate the exact whereabouts of game, and Spaniels also are widely used as gun-dogs. The other uses to which dogs have been put in field sports include hunting over rough and difficult country by small terriers, and going to earth to kill or hold badgers, foxes, and otters. Fox Terriers, Dachshunds, Dandie Dinmonts, and Scottish Terriers are among the types which have been so employed. Dogs have played their part also in entertainment: thus there are performing dogs, notably the Poodle, and racing Whippets and Greyhounds, while in former times various types of fighting, including the baiting of bulls by Bulldogs, were to be seen. The use of sledge-dogs is well known, while in Belgium and elsewhere dogs were at one time widely used as traction animals. In coaching days, the Dalmatian was a carriage dog, and modern scientists have recently suggested, as a result of experiments, that the position under or behind a coach which a Dalmatian automatically takes is determined by heredity! Perhaps the most exacting use to which man has ever put dog was in China, where the Chow-Chow was once maintained as a source of meat and fur! In Portugal, fishermen employ a race of dog to accompany their fleets. The dogs in question (Portuguese Water Dogs) will dive into the sea to retrieve a broken net or an escaped fish, and will even swim from one smack to another to convey messages! In New Guinea native dogs act as scavengers, while in various countries on the Continent of Europe "truffle dogs" are employed to locate the fungi known as truffles, relished as a table delicacy.

The above paragraph is far from exhaustive, and for those who wish to know more of the characteristics of the different varieties of dogs, reference should be made to such volumes as *Book of the Dog* by Brian Vesey-Fitzgerald (2 guineas) or *Working Dogs of the World* by C. L. B. Hubbard (16*s*.). For general guidance on dog management, see *The Right Way to Keep Dogs* by R. C. G. Hancock (5*s*.).

For present purposes it is, however, as a pet or companion that we are considering the dog, and it must be agreed that many of the most successful animals for this purpose are cross-breeds or "mongrels." There are many fallacies or unsubstantiated generalisations regarding the relative merits of pure-breds and mongrels. This is in fact an intricate scientific problem, and probably the simplest way of summarising the true position would be to say that, from the point of view of health and temperament, there are good, bad, and indifferent specimens among pure-bred and cross-bred animals. It is true that within a breed (or within a local community of mongrels for that matter) certain weaknesses or undesirable traits may arise from hereditary defects.

It may be noted that the word "dog" is applied to the whole species, although it is used also to denote the male as opposed to the female, for which the correct term is "bitch." Young animals are referred to as "dog puppies" or 'bitch puppies" respectively. A male animal employed regularly for breeding is known as a "stud dog," and the corresponding female as a "brood bitch." In hunting circles the Foxhound is referred to as a "hound," and the term dog and bitch are employed only as prefixes to denote the sex.

CHOICE OF DOG.

However attractive the idea of keeping a dog may be, it is unwise and unkind to purchase or to accept one without very careful consideration. Dogs require regular feeding, grooming, and exercise and, if they are to be allowed to show their full capabilities, constant companionship and attention. Nothing is more pathetic than the unwanted dog, which may have been purchased because of a passing whim, and with which no one appears to have the courage to part. If, on the other hand, one is prepared to give all the necessary time and trouble to the proper care of the dog, the reward will be ample.

The size of the choice is important. Many people keep dogs which are far too large for their houses and for their purses. The smaller the dog, the less food, exercise, and house-room will he need, and the many varieties of terrier provide a range from which suitable choices for most households may be made. In any event, a very large dog should not be chosen unless expert advice has been taken about his feeding and other requirements.

Household dogs of six months of age or over must be licensed. Licences may be obtained from any post office.

MANAGEMENT OF THE DOG.

Accommodation.—Up till comparatively recently most dogs were kennelled down out of doors. This practice has its advantages, but to-day the majority of pet dogs are allowed more or less the run of the house. A warm sleeping-place, such as a box or basket, should be provided, and should contain removable bedding. Newspaper is an excellent non-conductor of heat. It is a very useful material to place at the bottom of a dog's box; and on two or three thicknesses may be placed a rug or blanket on which the animal may lie. It is astonishing the amount of grit and dust a dog can bring into a house on his limbs and the lower part of his body. His bedding will require frequent shaking out and renewal, and paper is easily changed. The box or basket in which the dog lies should be allowed a place free from draughts, and requires airing daily when the dog leaves its bed in the morning. Wood-wool makes excellent bedding in outhouses or where a special structure is provided by way of dog-kennel, but is inclined to be messy about the house, as a dog will draw portions of it about the room as he leaves his bed. If straw is used, it is best stuffed into a sack and made into a kind of mattress. An odd piece of linoleum forms an excellent foundation to the dog's sleeping-box or kennel; it does not strike cold to the skin, is a slow conductor of heat, and has the advantage of being easily kept clean, particularly during illness, when there may be discharges and messes to be frequently cleaned up, until the animal can once more go out of doors.

Exercise.—Every dog should be exercised regularly, but there is no need to over-exercise,

and the practice of allowing a dog (other than a large and athletic animal) to run behind a bicycle for mile after mile cannot be too strongly deprecated. Two or three fairly short walks a day are sufficient for a small terrier, always provided that there is a garden in which he can play on fine days and some open space where he can run freely for a short time. While still in the puppyhood stages, a dog should be trained to walk to heel and to beware of traffic. Even so, it is usually safer to put him on a lead in busy thoroughfares. One point which, to the annoyance of the public, many dog-owners fail to realise, is that their animals would show much less tendency to fight if allowed to investigate one another off the lead. A dog naturally feels aggressive if put on the lead immediately a rival hails in sight. There are, of course, certain dogs which attack others at sight; these are a public nuisance, and should never be allowed loose on the streets.

The practice of allowing a dog to take his own exercise is to be deprecated, especially in towns and suburbs. The animal will be tempted to sniff into dustbins, and, if a male, will tend to follow a bitch in season or to take part in the unsavoury "dog parties" which are so often to be seen. Furthermore, such an animal is usually responsible for the disgusting habit of fouling the pavements and gateways. In this connection, it should be emphasised that dogs may quite easily be trained to defæcate in the gutter, or on the grass verge, and so avoid contamination of the pavement or carriage-way. In some districts owners are liable to a fine if their dogs foul the pavement.

Training.—Patience combined with the gift of putting yourself in the dog's place is the chief requisite for successful education. It is most important to encourage regularity of habit, as an animal will obviously learn very much more quickly if his daily walks, meals, and grooming take place at fairly constant times. A quiet firmness is the ideal method, and a puppy should learn early that a command *is* a command, and must be obeyed. There is no need to shout and make an exhibition of oneself, or to race in circles after a disobedient puppy; if these things are done, the animal will never become so well trained as it otherwise would. Again, it is rather ridiculous to chastise a puppy *after* he has somewhat belatedly decided to come to heel; quite obviously, he will then be liable to think that he has done wrong in actually coming to heel. Whatever happens, it must never be that the dog becomes master; there is no more unbecoming sight than that of a person with a frankly disobedient dog, and if the animal be large and powerful it may prove a menace to its owner and to the public.

Puppies should be house-trained at an early stage. If care and thought are given to the matter, the animal will soon learn not to make messes in the house. However, it is very stupid to forget all about a puppy or dog for many hours, and then, out of sheer vexation, chastise it for having made a mess. If puppies are let out every two hours or so at first, they will soon learn not to make a mess. Encourage them for performing in the right place rather than scold them for doing so in the wrong one. Physical punishment should be administered only where strictly necessary, and then in a sensible fashion. The most effective method is to grasp the dog or puppy by the skin of its neck and to shake it.

Grooming and Washing.—Whilst short-haired breeds need little or no attention to the coat, bar an occasional brisk rub down with a brush or rough towel (which incidentally puts a pleasant gloss on the smooth-haired breeds), yet with the long-haired breeds grooming should be carried out regularly, and if the habit is made a daily one it will not be forgotten so readily. Nearly all dogs love this procedure, and most dogs will actually ask for their daily groom by jumping on the table or bench on which it is carried out. Steel combs and brushes are sold by many shops, principally corn chandlers, though some store chemists also provide a suitable range of grooming kit for all breeds. There is a curious fetish current among many breeders that dogs should not be washed. There is no reason why, with a few simple precautions, a dog should not be washed whenever it is socially necessary. The first precaution is to use a soap that does not contain an excess of soda. The strong washing-up soaps, excellent as they are for certain purposes, are too irritant for a dog's skin. While some of the toilet soaps suitable for human use may be employed for dogs, the special dog soaps and shampoos are much better for the purpose. They are more suited to the dog's skin and coat, and have better detergent properties. It is important not to have water that is too hot—as with a baby's bath, it should be possible to dip the point of one's elbow into the water and find that it gives a pleasantly warm sensation but is easily bearable, *i.e.*, it should not be above 95–100° F. On emerging from a bath a dog will shake himself thoroughly, and then, if not curbed, will roll on the floor or ground and speedily cover himself with dust or dirt! It is therefore necessary to give him a brisk rub down with old (but clean) towelling, whereupon he may be allowed to dry off in a warm place free from draughts or, in good weather, put on a lead and taken for a brisk walk. In the case of many of the long-coated breeds it is customary to have them trimmed at the beginning of summer, and this is a sensible precaution that may avoid a good deal of distress during hot weather. The smaller long-haired dogs in particular, such as Scottish Terriers, suffer unduly from the heat if their coats are grown too long.

FEEDING OF THE DOG.

Meat, usually beef, is generally regarded as the staple article of the dog's diet. It must be pointed out, however, that although the dog is naturally a carnivore (flesh-eater), ordinary meat (muscle or "flesh") is not a completely adequate diet, and lacks certain factors which the wild dog would find in the blood, bones, liver, and other organs of his prey. Furthermore, it has been proved scientifically that dogs can thrive on a meatless diet. In spite of these reservations, however, meat must be regarded as an excellent article of food, and if properly supplemented will prove very satisfactory. In recommendations which have recently been made in America (Dr S. R. Speelman, of the U.S. Department of Agriculture) it is suggested that meat (beef, lamb, mutton, or horseflesh, providing that the last is fed regularly and not spasmodically) or meat substitutes (fish, milk, eggs, etc.) should constitute one-half of the daily ration, and that the remainder should comprise approximately equal parts of cereal substances (bread, biscuits) and of vegetables (carrots, spinach, onion, beet, etc.) It is pointed out that many dogs do not accept the vegetable material readily. On this basis, the approximate quantities of food required by adult dogs have been calculated as follows:—

Weight of dog.	*Total food per day.*
1 lb.	2 oz.
10 lb.	12 oz.
25 lb.	1½ lb.
50 lb.	2 lb.
75 lb.	3½ lb.
100 lb.	4¼ lb.
150 lb.	5¼ lb.
225 lb.	7 lb.

(Weights of up to 10 lb. would include the toy breeds, 25 lb. would correspond to a Fox Terrier, Airedale Terriers and Retrievers would fall into the 50–75-lb. class, and the larger weights would be those of the very big breeds, such as the St Bernard.) The quantities given are, of course, an *approximation* and no more. Dogs which lead a very active life will require more, while those which take little exercise, or which tend to put on fat easily, will require less. Common sense is necessary, and great care must be taken not to over-feed or to under-nourish.

Meat is probably best fed raw, or lightly cooked, but many animals appear to have a preference (probably through habit) for well-cooked meat. In any event, the meat should not be "overdone," as there is substantial evidence that prolonged heating destroys much of the food value of the meat protein. *Fish* is an excellent substitute. There need be no anxiety about the greed with which a dog swallows lumps of meat and also neglects to masticate them. The teeth of the dog are for tearing meat, he is not concerned

with biting his food up small; indeed, his salivary glands contain no digestive ferments, as is the case with some other animals.

Milk is almost essential during pregnancy and lactation (see below), and may well be included in normal dietaries. Whether or not *bones* should be fed is a matter which has been hotly debated, but for mature household dogs the evidence suggests that they are unnecessary. (The teeth of racing greyhounds, which receive a "sloppy" diet, are quite as good as those of the average household dog.) Bone-feeding is responsible for much trouble, including constipation, actual impaction of the rectum, and lodgement of pieces of bone in the mouth or throat. The value of bones is, of course, that they contain large quantities of essential mineral substances, and for this reason the inclusion in the diet of bone-meal, or of steamed *bone-flour*, or, preferably, a mineral supplement, is recommended. Only very small quantities of these substances are required.

Bread is an article of food which is often overlooked in the case of the dog, but there is no doubt that wholemeal bread is very suitable indeed, provided it is not fed to excess.

The answer to the question whether a dog requires vegetables is, in the main, no. From the Vitamin C standpoint they are quite unnecessary, since it has been shown that a dog manufactures this vitamin for itself, but the fact remains that many dogs, particularly of the toy variety, enjoy a few slices of banana or apple, and there is no harm in letting them pander to their taste. Vegetables do help, however, to provide roughage, and cooked (*not* raw) *potatoes* may be used in place of bread or biscuits. The dog—like many other animals—cannot digest raw starch properly. *Flaked maize* and *oatmeal* are other substitutes, but it must be remembered that the energy value of maize is high and that the dogs must never be overfed. *Dog biscuits* are an item that were long in disfavour with some professional people on account of their often having been made from agenised white flour (see section on Canine Hysteria), but now that this factor has been overcome, and the biscuits themselves are being improved in other ways, their use for the non-meat portion of the diet may be recommended.

Clean fresh *water* must be provided at all times.

In addition to the diets recommended above, there are on the market several tinned dog foods which claim to be complete, or almost complete, diets for the dog. It must be said that many dogs (including those of the writer) have remained in excellent health when receiving one of these foods as a large part of the diet over long periods. There is, therefore, little that may be said against the widespread use of the better varieties of such products. Again, it is a matter for common sense; if an owner finds that his animal is thriving on such a diet, he is wise to continue to use it.

It is customary to give dogs two meals a day. There is no need to give more than two to healthy adults, for the dog's stomach is exceedingly capacious and adapted to long gaps between meals. Many dogs thrive on only one meal in twenty-four hours. Whatever plan is decided on, regularity should be adhered to, and a meal or meals given at the same times every day. Dogs require vitamins A and D and B complex. There are several ways of administering these, but the special commercial preparations, including the modern form of condition-powder tablet, are the most convenient.

The *pregnant* and *lactating bitch* require special consideration. The food requirements are very much increased in a bitch which is carrying puppies, especially towards the end of the period. Normally, appetite is not a complete guide to a dog's food requirements, but in pregnancy and lactation the bitch must not be allowed to go hungry. It is quite normal for a heavily pregnant bitch to require over one and a half times her normal amount of food, and in lactation her requirements will increase still further. Milk is a most excellent article of diet at this time; indeed, there is no better way (apart from commercial preparations) of replacing the milk which the bitch is giving to her own puppies.

Up to the age of three weeks or so, *puppies* need have mother's milk only, but at any time after this it is a sound policy to give them additional food, and so spare the mother and also render weaning (at from six to eight weeks) a *gradual* process. At first a little cow's milk or one of the commercial "dog-milk" preparations may be given, and gradually the puppies should be encouraged to eat solid food. Eggs (if they can be spared), wholemeal bread in milk, or even finely minced meat may be given, at first in very small amounts but later in larger quantities. If this process is carefully carried out, there will be far less trouble at and after weaning time. After weaning, puppies should receive five or six meals a day, and this number may be cut down gradually until two or three only are given to the fully grown dog. (The smaller breeds are fully grown at about a year.) *More* meat or meat substitutes and milk, and *less* cereal or vegetable matter, should be fed to the growing dog as compared with the adult. This fact is important, as the substances present in meat and milk are required for laying down the growing tissues. Nevertheless, the energy portion of the ration is important, and the cereal or vegetable should be nutritious and not fibrous. It is possible to rear puppies by hand from birth if the bitch for any reason should die. It requires great patience for the first two or three weeks, as naturally the puppies will require feeding once or twice during the night. Special milks for puppies are to be recommended. Cow's milk requires enriching with fat and sugar to approximate to the composition of bitch's milk. Feeding will have to be done at every two or three hours, and a very useful gadget is a fountain-pen filler attached to cycle-valve tubing. Very small quantities are required for the first two or three days, and a level teaspoonful of milk is more than sufficient for the average terrier at first. Even with the best care in the world hand-fed puppies tend to be weaklings and do not grow as fast as those naturally fed. A foster bitch, if obtainable, is much to be preferred.

BREEDING OF DOGS.

It is natural for adult dogs of both sexes to wish to breed, and in the case of the female especially it is an excellent thing if one can arrange for a suitable mating to take place. Bitches come "into season" or "on heat" (lay terms for œstrus) at approximately six-monthly intervals, but it is not advisable to breed from the first season which occurs usually at about eight to nine months of age, but over a wide range of age according to breed and other factors. The periods of season often occur between January and March and in early Autumn, but there is no fixed rule. Each season lasts for three weeks. For the first seven days, approximately (pro-œstrus), a bitch does not permit mating, though during this time she is a source of strong attraction to all males in the neighbourhood. At about the seventh to the tenth day the blood-stained discharge, which ushers in the heat, stops; this is usually taken by the breeder as an indication that the bitch will stand to service. If possible, it is always better when puppies are wanted to allow mating to occur more than once. Under natural conditions a dog and bitch are usually strictly monogamous and mate for life, and during the period of œstrus will mate many times. A dog and bitch that are kept together all the time will probably behave naturally, but under domestication both dogs and bitches usually become promiscuous. Many bitches will in fact accept service from different males on different days, and the phenomenon of superfecundation, *i.e.*, the production of a litter that is fathered by *two* males, may occur. It is therefore wise to retain strict control of the bitch throughout the whole of the three weeks or so she is in season. At the end of season the bitch passes into a state of "metœstrus" if she has not conceived.

If a bitch conceives, she carries her puppies for a period of about nine weeks. There is, however, a normal variation of fifty-eight to seventy days, and puppies born before the fifty-eighth day sometimes live. The number of puppies born varies with breed; in the smaller terriers it is usually from four to six, but in Airedales and Alsatians the number may be eight to ten, and the larger breeds tend to have even more offspring at a time. Birth usually takes place fairly easily in the larger breeds, but there is often much

difficulty in the case of the short-legged breeds, such as Scottish and Sealyham Terriers, Pekingese and Dachshunds. In some breeds, in fact, the problem is one that is giving serious concern to veterinary surgeons and breeders.

A short while before her puppies are due, a bitch will "make her bed." Owners are often amazed at the destruction of soft furnishings, or even of wall-paper, that a previously well-behaved bitch may carry out at this time; it is therefore by far the best to provide a suitable box (if the animal has not one already). A smooth flooring such as a strip of linoleum serves for the bitch to give birth to her puppies. Her instinct to tear up everything given to her for bedding may lead to suffocation of the puppies by pieces of bedding. Provided labour occurs in a warm room, it is sometimes better—according to the temperament of the bitch—to remove each puppy as it is born, placing a warm bottle underneath, and bring it back to the mother when the last birth has occurred. At this time the bitch should be watched carefully for any discharge from the vulva or for any evidence of straining. If either of these occurs without results, it is advisable to send for help as early as possible, especially in the case of the smaller breeds. Many hundreds of bitches are lost through neglect at this time, and usually because it was not suspected that anything was wrong. If the discharge becomes bloody, or green, help should be obtained *at once* if no puppy is delivered. Similarly, any great delay between births is a matter for concern. The afterbirth usually follows the puppy within a few minutes, but puppies are sometimes delivered in their fœtal membranes, and in this case the latter should be gently but quickly removed. It is quite normal for the umbilical cord to remain attached to the puppy, but the bitch will normally break it by biting through it.

The mother will wash and attend to the new born puppies, and after the last is born it is a good idea to burn all the mess and to provide clean newspaper, but do not worry or frighten the bitch more than is necessary. For the care and feeding of the bitch and her puppies see the sections on Management and Feeding. Puppies, like kittens, are born with their eyes closed, but open them after about nine days—there again being considerable variation.

The phenomenon of pseudopregnancy is common in bitches, and indeed to a minor degree it is probably present in most bitches following an œstrus without conception. In some bitches, however, presumably those with strong maternal drives, the changes in the ovary may be accompanied by external signs of "phantom" or "ghost" pregnancy. These may include not only enlargement but actual functioning of the mammary glands, and the making of a "nest" by the bitch just as if her puppies were really due. The average duration of pseudopregnancy is usually given as about two months, and although variable, it is often sufficiently near to the correct time after œstrus that everyone suspects the bitch to be truly pregnant. The condition may be suppressed with the aid of modern drugs, but in some instances it is not realised that the condition is not real. In many cases only professional advice can solve the mystery, and radiographical examinations have often proved necessary to ascertain the truth, particularly in fat bitches of the heavier breeds. It might be well to note, at this point, that there is another condition of the older bitch that is known as *Pyometra*. This condition usually reveals itself at the same time as the ghost pregnancy (and is sometimes a pathological extension of it) but is accompanied by considerable disturbance of health, coupled in many instances with purulent discharge from the vagina. A bitch which is off-colour in the weeks following pregnancy, or which develops a discharge from the vulva (especially one which is dark in colour), may well be a pyometra subject. The disease is most serious, and often requires surgical intervention. As the best chance of success is to operate or otherwise deal with early, a veterinary surgeon should be consulted immediately.

DISEASES AND INJURIES OF THE DOG.

Canine Distemper and "Para-distemper" (Including so-called "Hard-pad").—It has long been recognised that the commonest and most serious disease of dogs throughout the world is canine distemper. Dogs of all ages and breeds are susceptible, and no dog is free from the risk of infection unless it has recovered from the disease or has acquired an immunity for other reasons. (For a definition of "immunity," see Medical Dictionary.) The disease is caused primarily by a minute agent known as a filterable virus (see definition of "viruses" in Medical Dictionary), which may be of varying type in that it will attack the body in different ways. Thus some strains of the virus are known as "neurotropic" because they show an affinity for the nervous system. Sometimes a dog will apparently recover from an attack of distemper, only to succumb later to "fits" or other nervous manifestations due to permanent damage to the central nervous system by the virus. Often, however, the virus is not fatal in itself, but will lower the dog's resistance and permit the entry or the activity of bacteria that may lead to pneumonia or other serious effects. These so-called "secondary invaders," as the bacteria are termed, may prove as harmful as the original virus. Indeed, once these bacteria have set to work it is too late to expect the best results from the use of serum, and whether or not the dog will live through will depend upon the severity of the attack, the dog's powers of resistance, and good nursing. It is therefore most important either to prevent the disease by vaccination or to be able to send for veterinary attention (and hence for an injection of serum) *immediately* an attack is suspected. Any puppy which is listless or off its food, or which may throw a fit, or which is obviously unwell with other symptoms (*e.g.*, cough or diarrhœa) may well be in the early stages of distemper, and it is *then* (not the next day) that help should be sought. Many thousands of puppies (and older dogs) that have been injected with serum in the early stages of the disease have become perfectly normal within forty-eight hours. On the other hand, the number of dogs that die in Great Britain alone from distemper and distemper-like infections must assume enormous proportions. Distemper is a highly infectious disease, and it is important that the owner of an infected animal should do his best to avoid contact with other dogs, ferrets, or mink. Ferrets and mink are very susceptible to canine distemper. On the other hand, human beings and cats are *not* susceptible to canine distemper, and the so-called distemper of cats is quite a distinct disease.

A highly satisfactory means of vaccinating puppies against distemper was worked out about 1926–30, and this—named the "Laidlaw–Dunkin" after its two inventors—has since afforded protection to thousands of animals. Vaccination consists either of the "vaccine-virus" method, in which a vaccine (see Medical Dictionary) is injected first, followed usually after about fourteen days by an injection of the virus, or of the "serum-simultaneous" or "serum-virus" method, in which a puppy receives two injections on the same day, one of virus and one of serum. Other means of conferring immunity have since been developed, including the injection of modified virus, *i.e.*, virus that has lost its power to produce disease but has not lost its power to call forth the antibodies that protect against the infection. A suitable modified virus is now grown on developing egg embryos.

There have, from time to time, been reports of "breakdowns" in dogs vaccinated against distemper. Sometimes these may have been due to the fact that the organisms that act as "secondary invaders" in distemper may sometimes set up disease on their own account should resistance be lowered from other causes. It has become increasingly realised, however, that many such breakdowns were due to an infection which, while closely similar to canine distemper—and in all probability a variant of it—was sufficiently different not to be controlled by the antibodies to ordinary canine distemper. From the fact that one of the features often seen in such cases was the presence of corn-like lesions on the pads of the feet, this infection has been termed "*hard-pad*." The term is not really very suitable, for hard pads are not a constant feature and do not appear until the disease has been active for some days. The earliest symptoms are often nervous in character.

"Hard-pad" can, of course, attack unvaccinated as well as vaccinated dogs of almost all ages and since the war it has probably been more common in Great Britain than "ordinary" forms of distemper. A suitable method of vaccinating puppies is now available for use against both the forms of distemper, *i.e.*, protection is afforded against the "hard-pad" as well as the other type. This vaccine, prepared from virus grown on the developing egg enbryo, is now widely employed in place of the "Laidlaw–Dunkin" methods described above.

Rubarth's Disease.—Another virus disease of dogs (and foxes) is known as Rubarth's disease, after one of its discoverers, or sometimes as infectious hepatitis. This disease has been recognised in Sweden ever since the 1930s, but in Great Britain only since the end of the war. The condition is extremely sudden in onset, and an affected dog may be found dead. Many cases are, however, mild, and in some instances only one or two out of a large group of dogs have been affected. The changes seen after death vary, but the findings in the liver cells are usually characteristic. Specific treatment is not yet established as in the case of the distemper-like conditions, although the administration of antibiotics (see Medical Dictionary) may prevent the effects of secondary infection.

Canine Hysteria (called "fright disease" or "running fits" in the U.S.A.) is an alarming but not necessarily serious condition (in that it can often be cured very readily) which appears to arise from a variety of exciting causes. The affected animal rushes around wildly, often screaming and howling, and obviously loses all sense of whereabouts or ability to recognise people. After a more severe attack (and there are all degrees up to a full epileptiform fit) the dog may appear quite exhausted, but returns to normal. Sometimes there are many attacks in one day. The dog will not wilfully attack people during a bout of hysteria—at least, that has been the experience of the writer—but is very difficult to control. Apart from ensuring that the dog does itself no grievous bodily harm, there is little that can be done until the attack has subsided. Then the animal should be kept as quiet as possible and given a sedative such as potassium bromide, of from 10 to 60 gm. (*i.e.*, from two to twelve 5-grain tablets), pending veterinary attention.

Hysteria may be an hereditary taint, derived from one or other parent. In certain circumstances, however, it may arise in apparently normal animals. There are several possible causes (including parasites), but a definite one is the bleaching agent—nitrogen trichloride or "agene"—employed for some years in the manufacture of flour, and hence present in white bread and certain dog biscuits. Indeed, the clear demonstration that agene could set up hysteria in dogs, and subsequent scientific work, has led to the introduction of regulations that have led to its abandonment as a bleaching agent in favour of other methods which have been found not to cause hysteria. There has already been a marked decline in the incidence of hysteria due to dietary factors.

Rabies is a fatal disease of dogs, and is also due to a "filterable virus." It is transmissible to the human being and to many other species, but has fortunately been absent from Great Britain for many years. Stringent precautions are taken to prevent its entry, and dogs which are brought into Great Britain must spend a long period in quarantine.

Tonsilitis appears quite frequently in dogs, and seems in many cases to be part of a more generalised infection. It demands expert treatment, but although it may persist for a long time, it usually yields to treatment.

Nephritis.—Inflammation of the kidneys is unfortunately all too common in dogs, and in adult males in particular there is a high incidence of chronic kidney damage. One of the symptoms is a marked thirst. Sometimes this condition is a sequel to an infection known as *leptospirosis*, which calls for prompt veterinary treatment if death or permanent damage is not to follow. It is always worth while seeking professional advice for a dog that drinks excessively or has a somewhat characteristic type of bad breath.

Anal Glands, which are found in the dog and in other carnivora, often give rise to trouble. Animals which "rub themselves along the ground" are not necessarily affected with "worms," but with impaction of these two little glands, which are situated one on each side of the anus. They secrete a peculiar dark-coloured, very offensive fluid, which sometimes is not discharged properly and causes the animal great discomfort. The glands in such cases should be relieved periodically. Those who do not mind this somewhat dirty task may perhaps learn how to do it themselves. Occasionally, segments of tapeworm are responsible for the impaction, but usually the trouble has nothing to do with worms. Whenever a dog pays considerable attention to his anus, this impaction should be suspected. Actual infection of the glands is also fairly common, and demands expert attention.

Diseases of the Ear, especially of the outer ear, are very common in dogs. The dog's outer ear is somewhat more complicated than is our own, and the drum is set more deeply. Hence it is easy for wax and dirt to accumulate, for various parasites to establish themselves, and for inflammatory conditions to result. The word "canker" (which has no precise scientific meaning) is sometimes applied by lay people to the more serious or chronic forms of inflammation of the outer ear canal. It is not difficult to diagnose "ear trouble," as the affected animal usually shakes its head or worries or scratches its ear and rubs it along the ground. The ears should be inspected regularly to see that there is no great accumulation of wax or dirt. Cotton-wool twisted on to the end of a match-stick or orange-stick is quite satisfactory for cleaning out the ear, providing care is taken. A dog which is continually worrying its ear, or which has ears which are obviously diseased, should not be neglected, as the sooner expert treatment is begun the more readily will the condition be cured. Even if the lining of the ear is greatly thickened through inflammatory reaction, and the lumen nearly occluded, it is still possible for a plastic operation to be performed. Many hundreds of such cases have been successfully treated in this way. A considerable percentage of inflammatory conditions of the outer ear is associated with ear mange mites. A considerable proportion—possibly 50 per cent—of cases in dogs in Great Britain has a parasitic origin. In such an event treatment with modern anti-mange preparations should be carried out.

Deafness in certain white dogs (*e.g.*, in some Bull Terriers) appears to be hereditary, and is quite incurable. Old dogs often become deaf, and deafness has been produced experimentally in young puppies by feeding them on a deficient diet.

Diseases of the Eye are very common in dogs, and are often the result of injury. Except for minor discharges from the corners of their eyes (and in younger dogs especially it must be ascertained that these are not a symptom of distemper or secondary infection) any eye disease is sufficiently serious to merit professional advice. Boracic lotion is not suitable for the eyes of dogs. It is slightly irritant, and dogs are apt to scratch and make the eyes raw after application. Colloidal silver eye lotions and ointments are far more suitable pending the advice of a veterinary surgeon. In eye inflammation avoid sunlight and wind. For some days in the early stages of inflamed eyes, the light in the room should be subdued. Pekingese seem to be especially prone to eye disease, but the remarkably unwholesome appearance of some affected eyes in this breed is not necessarily evidence that recovery is unlikely.

Steps should be taken to ensure that the dog does not inflict further injury on an already diseased eye. Cat scratches are a frequent source of inflammatory conditions of the dog's eye. Eyes must never be neglected, for the consequences are serious.

Skin Diseases are common in dogs, and may be contagious—as they are in the majority of instances—or non-contagious. Apart from the inflammation of the skin that occurs in spring and autumn, during the shedding of the winter and summer coats respectively, by far the commonest cause of diseases are the skin parasites: fleas, lice, and mange mites. Owners are often horrified to learn that their dogs are infested with these creatures, and in a few cases filthy home surroundings will lead to the dog being infested with the human kind of flea. Far more often he has his own particular variety of flea, and there need be no shame on the part of the owner. Moreover, many fleas, such as those of the rabbit, the rat, and the hedgehog, will transfer themselves to the domestic dog during his peregrinations. Treatment of these parasitic diseases has been revolutionised in these last few years by the use of D.D.T., benzene hexachloride (Gammexane) and other modern preparations. Apart from those obvious infestations of fleas and lice, skin complaints of a persistent nature, of which the cause is not obvious, should be placed in the hands of a veterinary surgeon.

Diseases of the Teeth and Gums are very common in household dogs. A serious systemic disease, such as distemper, may leave the enamel of the teeth permanently pitted, hence "distemper teeth." More serious than this, however, is a form of pyorrhœa, which is really a disease of the gums rather than a primary disease of the teeth themselves. The margins of the gums become red and swollen, and may bleed easily. As the condition progresses the teeth may become loosened. Particles of food become lodged between the teeth or between teeth and gums, and add to the inflammation and to the smell of the breath.

This disease may, if unchecked, become very serious. In many cases extraction of one or more teeth is indicated, but unfortunately it is not always possible to do this. The condition demands expert attention.

Another common condition of dogs' teeth is the deposition around them of "tartar." This should be removed by scaling or by special use of dental forceps. Some breeders and others may themselves have learnt how to carry out these operations with the requisite skill and care, but they are not easy to the amateur, and it is essential that no harm be done to the animal's soft tissues by injudicious use of the instruments. Ordinary dog-owners are strongly advised to take their dogs to a veterinary surgeon in order to have the "tartar" removed.

Most puppies lose their first or "milk" teeth quite regularly between the ages of three and five months, but sometimes there is difficulty and the primary teeth are not shed properly. These cases should be treated by a veterinary surgeon before the permanent teeth are thrown out of their proper alignment.

One hears very much about "teething fits" in puppies, and while these occur, owners should be *very* careful to ensure that a "teething fit" is not a sign of distemper, which often starts with a fit. As puppies of this age are so susceptible to distemper, it is advisable to seek professional advice should any form of fit occur. It may save much time, money, and trouble, and even the animal's life.

Internal Parasites: "Worms."—It is probable that more nonsense has been talked and written about "worms" in dogs than about any other canine subject. According to some people, "worms" are the root of nearly all doggy evil, and so long as a dog is regularly "wormed" all will go well with him. These beliefs are frankly absurd. The real facts are very different, and are stated in as brief a fashion as possible in the following sentences. In this country dogs are infested by a species of "roundworm" (a creature which is a dirty-white colour and in shape somewhat resembles the common earthworm) and by several species of "tapeworm," which are also whitish but which are flat and are made up of many small segments joined to a little "head" which is attached to the lining of the gut. In spite of all that is said, tapeworms as such are rarely responsible for much harm to the dog, although they can, of course, prove debilitating and should be removed. They are a nuisance, and attempts to remove them should be made by administration of the appropriate drug. Occasionally, segments of worm are responsible for impaction of the ducts of the *anal glands* (see above).

The roundworms may be extremely serious in young puppies, in which they cause stunting, "pot-belly," harshness of coat and dangerous or fatal illness. Fortunately, modern anti-roundworm preparations are available for animals of this age. Once over the age of 4–8 months, dogs rarely suffer serious illness from roundworms, although these may cause occasional vomiting, or even diarrhoea, and some loss of coat and bodily condition. It seems probable that puppies are sometimes infected before birth from their mother. It is therefore desirable to keep down the incidence of roundworms in the mother—and in dogs generally—and fortunately the modern preparations are—unlike some of the old-fashioned ones—safe in use and unlikely to cause digestive disturbances. From all that has been said above owners will realise the necessity of taking professional advice about young dogs which are ill, and any signs of "worms" in young puppies—either in the stools or by some obvious intestinal upset or bloated appearance of the belly—should be acted upon. One last word about this aspect of worms—do not assume that your adult dog has "tapeworms" unless you see some evidence in his stools. There are so many "signs of worms" that veterinary surgeons must at times get a little tired of being assured that "My dog has worms" because of some trivial habit connected with appetite.

There is, however, another side to the study of tapeworms, and one which is not generally realised. The tapeworm which is found in the dog represents one stage in the life-cycle. The eggs, which are present in the ripe segment passed by the dog, develop, not in the outside world, but in another animal altogether. Thus one of the commonest tapeworms in this country has an intermediate stage, as it is called, in the flea, and it is when the flea is eaten by the dog that this intermediate stage develops further to become a tapeworm. Another tapeworm has an intermediate stage which develops in the sheep, and a third has one which develops in the ox. There is a fourth tapeworm which has an intermediate stage which *may* develop in man, to set up serious diseases in certain cases. Children may become infected through handling the dog, and so picking up the eggs, which may then be eaten through putting the hands in the mouth. The dogs which are most likely to be infested are those which have the opportunity to eat freshly killed sheep and other food-animals. An ordinary household dog is not likely to be infested, and people should not worry unduly in this connection, provided they do not allow their dogs to stray into the wrong places. It is illegal to allow dogs to enter a slaughter-house, but unfortunately one often sees dogs in such places. The routine worming of dogs is justified if evidence of infection exists, and certainly in country areas where opportunities of tapeworm re-infection may be plentiful.

Tumours, including malignant tumours ("cancers") are relatively very common in the dog—probably as common as in the human subject. Space does not permit of a detailed account, but the following examples of growths may be mentioned: a proliferation of warts on the skin of puppies (usually disappear spontaneously); a true cancer of the tonsil in middle-aged and older dogs of both sexes; cancer of the mammary glands in bitches (both incurable); fatty growths of the vagina of bitches (amenable to operation).

Space does not allow of the discussion of other diseases, but it should be pointed out that dogs are susceptible to human and bovine forms of *tuberculosis*, especially the former. In a household which contains a tubercular person, the dog should be watched for any signs of illness, and the thought entertained that he might be responsible for the further spread of the disease. For a discussion on ringworm see the appropriate heading in the section on the cat (F9).

Accidents and Injuries.—In these days of swiftly moving motor transport, street accidents to dogs are extremely common. Many could be prevented by training the animal to walk to heel, by the use of a lead in busy thoroughfares, and by not allowing dogs to roam the streets unaccompanied—a thoroughly bad habit. Sometimes the victim escapes with a scare and a few bruises, and at others death is mercifully swift. In the vast majority of accidents, however, a more or less serious injury is incurred, and if the animal is unable to move, the police should be notified immediately. The dog is best left quiet, and it is not recommended that attempts be made to administer brandy or other supposed "stimulants" unless help is markedly delayed. Excessive hæmorrhage may in some instances be prevented by common-sense application of principles learnt in first-aid courses.

One of the commonest accidents to dogs, especially to young dogs, is a fracture involving the head of the femur, or thigh-bone. Inability to put one of the hind legs to the ground, or to bear any weight on this limb, is an indication of such an injury. (This injury may occur also from falling off a chair or wall.) Professional help is, of course, required in such cases.

Cuts and Bruises, if not serious, may be treated at home as in the case of human beings. The indiscriminate use of tincture of iodine is not to be recommended, and spirit alone makes a more satisfactory dressing in most cases. Simple washing and removal of dirt are usually sufficient, combined, perhaps, with modern antiseptic ointments or other preparations. The dog (and also the cat) are very liable to sepsis, and it is best in such cases to send for proper assistance early, or there may be grave trouble. It is probable that in nature many of the flesh-eating animals end their lives as victims of the sepsis following wounds.

Injuries from cat-scratches are exceedingly common, as are bites from other dogs. These are serious, as they more readily result in septic places. The scratch or bite sometimes penetrates quite deeply, leaving a pocket which fills up with pus. This pus may spread under the skin to form sinuses. Never neglect such places.

There are a few concluding remarks on the treatment of the diseases of the dog:—

(1) It is not correct that "water should be withheld from a sick dog." It is true that an animal which is using water only to vomit, or which is drinking excessively, should have its water intake restricted, but it is wrong to deprive a dog altogether.

(2) There have been such wonderful advances in the field of veterinary anæsthetics that there is nowadays little to fear in this connection from operations to dogs and cats. The records over the past years at the Royal Veterinary College, London, and at other centres have been most encouraging, and the anæsthetic risk is now small indeed.

(3) When a dog's life is a burden to him, it is unfair to keep him alive, and he should be put to sleep. It must be realised, however, that putting a dog to sleep is a very skilled task. It is made much easier if an owner will allow his veterinary surgeon to administer an anæsthetic and not allow the animal "to come round," and shooting is also straightforward and painless if *skilfully* carried out. There are no "magical ways" of destroying human or animal life, and an owner must not expect his veterinary surgeon to be able to bring about death merely by holding a pad to the dog's face. It is far better that the task be carried out at a veterinary surgeon's own premises, where there is skilled assistance.

CATS.

Many of the general remarks in the preceding section apply equally to cats, and will not be repeated unnecessarily in the following paragraphs.

BREEDS AND VARIETIES OF CAT.

The following breeds and varieties are recognised for registration purposes by the Governing Council of the Cat Fancy:—

Long-haired Cats.

Black	Tortoiseshell
White (Blue-eyed)	Tortoiseshell-and-White
White (Orange-eyed)	Blue Cream
Blue	Brown Tabby
Red Tabby	Chinchilla
Red Self	Smoke
Cream	Silver Tabby

Short-haired Cats.

Black	Spotted
White	Russian Blue
British Blue	Manx
Cream	Abyssinian
Tortoiseshell	Siamese (Seal-pointed)
Tortoiseshell-and-White	Siamese (Blue-pointed)
Silver Tabby	Siamese (Chocolate-pointed)
Brown Tabby	Burmese
Red Tabby	
Mackerel-striped Tabby	

Pedigree breeding and showing are practised with a very small fraction of the total cat population of Great Britain, and the majority of these remarks will be concerned with the ordinary household cat. Nevertheless, in recent years there appears to have been a considerable increase in pedigree cat breeding. Registration—which is essential for showing and pedigree purposes—is controlled by the Governing Council of the Cat Fancy, of which the secretary (1958) is W. A. Hazeldine, 1 Roundwood Way, Banstead, Surrey. Many of the breeds listed above have their own societies, which are affiliated to the Governing Council. The addresses and particulars of these and other cat societies and clubs may be had on application to the secretary of the Governing Council. The two most popular varieties of cat are the Blue Persian and the Siamese, and an exclusive show is held for each of them. In addition to these shows there are five big Championship Shows open to every variety of long- and short-haired cat, while there are classes for cats and kittens at some of the Agricultural Shows.

CHOICE OF CAT.

Although there are, as noted above, many varieties of cat, most people are content to accept an ordinary kitten, and for them the chief points to consider will be: (*a*) whether to have a long-haired or a short-haired animal, (*b*) whether to have a male or female, (*c*) whether or not to have the kitten "doctored" (*i.e.*, castrated or spayed). As a general rule, short-haired cats are probably more suitable for the average household, since their fur does not become shed so noticeably and they probably suffer less from "fur-balling." Nevertheless, many long-haired cats are so attractive that they will obviously be preferred, and there is no reason why they should not be chosen. Sex is a rather more important question, although, as may be seen in the section on management, it is possible to have both males and females "doctored." Male cats which are kept as entires are often a nuisance in that they make abominable smells in the house and spend much of their time in fighting. These characteristics are by no means invariable; but they are so common as to justify the castration of the majority of males. Siamese males in particular may be a liability. Females are generally credited with a greater attachment to the home (although they wander when "in season") and with being better mousers. The principal objection to females is that they seem to be bearing kittens almost continuously. In normal circumstances it is, of course, quite impossible to prevent cats from mating by keeping the female in confinement

during her season, a practice which is frequently adopted in the case of the dog. For one thing, most people are never aware when their female cats are in season.

Whatever animal is chosen, it is essential to pick a healthy and preferably a fairly young—but *not* too young—kitten. It is best not to accept a kitten under about eight weeks of age.

For those who wish for something a little out of the ordinary, Siamese cats make excellent and highly intelligent pets. Siamese kittens are born white, but gradually develop their even pale fawn colour, with cream on belly and chest and with "seal brown" mask, ears, legs, feet, and tail. The coat is very short, and the eyes are blue. There has long been a popular belief that Siamese cats are delicate creatures, but the present writer has seen healthy specimens, kept under ordinary household conditions, living to a mature age. It is not wise to keep a male Siamese as a household pet. The male is a fierce fighter, and is generally a worse offender in the house than the males of other breeds, and should therefore be castrated if it is to be kept as a pet.

Many people find Manx cats attractive. Instead of the normal large number of tail bones, they have but three, and hence appear almost tailless. One should beware against fraudulent amputation of the tail of ordinary cats, which are then described as "Manx."

MANAGEMENT OF THE CAT.

The cat is an independent creature, so much so that one may say that to a large extent it manages its own affairs. This, however, is not true of all cats, and every reasonable attempt should be made to provide the cat with a comfortable and friendly home. Cats are highly intelligent, and if sufficient patience is exercised they will respond to a very great degree to human attention. Kittens should not be neglected, but should be talked to and played with just as are puppies. Many cats, especially young cats, make excellent playmates for children.

In order to prevent to a large extent their nocturnal wanderings, many cats of both sexes are castrated or spayed (the popular lay expression for this is "doctored"). In the male cat the testicles are removed by an operation which is almost always safe and simple if carried out skilfully. From three to four months is a good age at which to have this done. Female cats may also be "doctored." As the female glands or ovaries lie within the body cavity, this operation is a major one, but it is nevertheless quite a straightforward, though a more expensive, procedure if conducted at the right age (about five months). Many thousands of female cats have been so operated upon at the Royal Veterinary College, London, and the subsequent health of these cats is believed to have been excellent. Indeed, it has been said that a spayed female makes one of the best of all household cats.

Cats may choose to sleep in a variety of places, and will often lie on beds, chairs, mats, and other warm places. It is a sound policy to provide them with a box or basket, and to encourage them to use newspaper as a bedding. Most cats will take well to newspaper. The bed should be placed in a warm site—it is of little use putting it in a cold corner of a room and expecting the cat to lie in it.

Owing to the fact that, even in play, a cat's claws may inflict serious injury, dogs and cats do not always make the best of house companions. Nevertheless, the traditional enmity of cat and dog is often overcome, and if the two are brought up together they often make firm friends, sharing the same basket or hearth-rug and feeding together without serious consequences.

A cat normally attends to its own toilet, and everyone must be aware that a cat devotes long periods each day to cleaning and washing itself. Except in special cases, therefore, bathing is quite unnecessary, while in short-haired cats especially, grooming, too, is superfluous (this does not apply to show-cats). For some reason (and sometimes, apparently, because an owner attempts to assist in the daily grooming) an occasional cat may cease to wash or care for itself. Such an animal is a dejected sight, and should be taken to a veterinary surgeon to have its matted fur cut or combed, and its dirt removed. Such animals (unless they completely re-acquire their self-respect) must be groomed regularly if they are to be kept at all.

All household cats are accustomed to take their own exercise, and it is advisable (except in any special circumstances) to allow them free access to and from the outer world. Do not shut your cat in the house for a long period and then blame it for making a mess. Cats are clean creatures; they normally dig small holes in which to defæcate or urinate, and subsequently cover the deposit with earth. If, therefore, they are for some reason debarred temporarily or permanently from access to a garden, they should be provided with a box or tray containing soil or cinders. Indeed, in many types of houses it is a good plan to encourage kittens to use such a device. (Note the corresponding remarks about puppies.)

It is generally stated that "cats never forget a blow," and for that reason it is recommended that cats are not chastised. It may be said that, if a cat (or dog) be brought up conscientiously and well, it should never, or very rarely, require such punishment. An animal which has been brought up properly seems to develop a fair sense of what is right and what is wrong.

For pedigree cats, or those kept in confinement for other reasons, see the relevent remarks in the section on breeding.

FEEDING THE CAT.

Although most cats are capable of supplementing their diet by catching small rodents or birds, it is unwise to rely on this as a regular source of food. The idea that hungry cats make the best mousers is by no means always correct. Indeed, animals that are in poor condition are less likely to be successful hunters. Moreover, while the riddance of pests is an excellent matter from the human point of view—and one of the reasons why the keeping of cats is economically justified—the "cruel" fashion in which most cats tackle their prey is repulsive to most of us.

It is therefore necessary and desirable to provide regular daily feeding. Kittens should receive several meals a day, but by the time they are six months old the number of daily feeds should be reduced to one, or at most two. Most cats (many Siamese are exceptions) are extremely fond of *milk*, especially if it is creamy, and the cat's love of *fish* is well known. Many *meats*, especially *rabbit meat*, are relished, and a diet high in "animal protein" is indeed the aim, always provided that it contains sufficient "dietary energy." It is significant that cat's milk has a higher content of fat and sugar than cow's milk, *i.e.*, it is a richer source of energy. Some of the proprietary bitch-milk substitutes are nearer to cat's milk in composition than is cow's milk.

Many hundreds of cats have been reared and bred successfully in experimental laboratories on a diet consisting, in the main, of one part of fish or meat and two parts of *cooked potatoes*. This is relatively inexpensive, and may be supplemented by milk and by some of the proprietary cat foods.

Cats are also extremely fond of liver. Some of the proprietary cat foods—the better ones of which are excellent—and vitamin tablets contain liver, which is a rich source of the vitamin B complex.

Within reason a healthy kitten should be fed to appetite, always provided good-quality foods are available. The amount should be restricted when they are adult, however, except for pregnant and lactating cats, which are sometimes referred to as "queens" as opposed to the male "toms." An average daily allowance of solid food for a healthy non-pregnant adult cat should be of the order of ½ oz. per 1 lb. body-weight.

Cats are fastidious eaters; they usually sniff and examine carefully any strange or doubtful food. At the same time they are often greedy, especially with relished food to which they are accustomed, but fortunately they can, like dogs, vomit very readily. Here, incidentally, is one very good tip—an excellent emetic for both cat and dog is a small crystal of washing-soda, given as a pill. People are usually amazed at the way this simple device results in a dog's or a cat's bringing up undesirable food.

It is important not to overfeed cats, and it is

almost equally important to prepare all food in a clean manner, and to make it as attractive as possible. Cats will greatly appreciate this care. While milk is an excellent food for kittens (see under breeding), and is relished by most adult cats, it must be supplemented by solid food.

Clean fresh water should be provided at all times, even if the cat appears to drink it but little.

BREEDING OF CATS.

Pedigree animals are normally confined, and their breeding is strictly controlled. Ordinary household cats are at the opposite extreme, and there is little that can be done to prevent their mating. The length and scope of this article does not permit of a discussion of controlled mating.

Scientifically, there is as yet a good deal to learn about the reproductive behaviour of the cat. As an American physiologist has succinctly put it in a description of the reproductive cycle of the female cat, "No two authors agree." In Northern Europe there are two main heat periods a year, in spring and early autumn, but some animals may appear in heat at any time from January to July, and those who keep female cats in confinement describe their charges as "calling" quite frequently if not mated. A cat which is "in season" or "on heat" is often observed to be behaving in a quite characteristic fashion, rolling about on the floor and making peculiar sounds. The periods of heat, which commence usually at about eight months of age, may last for several days, and during this time the female will make every attempt to find a mate.

Gestation lasts about nine weeks, as in the case of the bitch, but here again there is a considerable variation. As most owners are quite unaware of the time at which their cats were mated, it is difficult to talk of "going overtime," but if there is any evidence of trouble during pregnancy, or at birth, veterinary advice should be obtained. As soon as a cat is obviously pregnant, her food allowance should be increased, and she should be allowed plenty of milk. It is highly important to increase her food and milk ration still further after the kittens are born, as lactation is a great drain on the mother.

Cats sometimes choose strange, out-of-the-way places in which to litter, and many healthy litters are born and reared out of doors. Rats are a source of danger, and will often destroy very young kittens during the mother's absence. For this and other reasons it is better in town and suburban areas to have the litter comfortably housed indoors. A wooden box containing newspaper is ideal, provided it is kept in a fairly warm place and out of the way of draughts. An average litter consists of three to six kittens, which are born blind, but which normally open their eyes after eight or nine days. There is no need to be alarmed if the eyes remain closed for a few days longer. Kittens which are born dead should be removed and buried or burnt. If the whole litter is born dead, the mother's food supply should be cut down considerably, and little milk given for a few days. If the mamary glands become inflamed, they may be bathed in a cold solution of alum. The glands normally return to their former size within a short space of time if they are not milked, but if there is persistent trouble veterinary advice should be sought.

While many pedigree owners wean kittens at four to five weeks of age, it is strongly advised that the household cat be allowed to continue to feed her family for a longer period, and eight weeks is not too long if the mother is still in good bodily condition. She *must*, however, be well fed and be allowed plenty of milk. As in the case of puppies, it is an excellent idea to provide the kittens with a little solid food as from a few weeks of age. It is very wrong to remove a kitten from its mother too early, and such an animal is often weakly, develops an intestinal infection, and dies as a miserable bedraggled creature. Moreover, during the period following weaning the mother educates her offspring in the art of living, particularly ratting and mousing.

As many litters are unwanted, some people get rid of all the kittens as soon as possible after birth. Drowning is frequently practised, but it is not recommended as a merciful death. Indeed, a hard blow on the back of the head is more humane if given accurately. It is much better to take the kittens to a veterinary surgeon or clinic.

DISEASES AND INJURIES OF THE CAT.

The principal infectious diseases of cats are still in need of much scientific study. It is now clear, however, that there are at least two major cat plagues. Both have been given many names, and there is much confusion between them.

Feline Enteritis or Panleucopenia.—This is a highly infectious disease, due to a filterable virus. The symptoms include loss of appetite, sometimes accompanied by a rise in body temperature, followed by listlessness, usually diarrhœa, sometimes vomiting, and a marked tendency to show tenderness or pain on being handled. This tenderness or pain is due to a developing peritonitis. The poor animal may become seriously ill, with loss of water from the tissues or dehydration, prostrate and dead within 48 hours or less from the time of the first symptoms. The incubation period of the disease is believed to be from 4 to 8 days, or sometimes longer. There is a fall in the white-cell count of the blood, hence the term "panleucopenia." Some cats recover, the recovery rate in different outbreaks that have been studied ranging from 30 to 80 per cent., and recovered animals are probably immune to further attacks. Cats that are able to take a little food during the early stages of recovery have the best chance of recovery, but require careful nursing. There may be complications during the convalescent stage due to secondary bacterial infections or to vitamin deficiency, and a light nourishing diet, combined with vitamin preparations, is recommended. Fleas may transmit the disease to other cats, as may contact with infected materials. It has been shown that bedding and dirt trays from sick cats were infectious for other cats for up to 16 days. The disease is not transmissible, to dogs or to human beings. There is nowadays a protective vaccine, and it is a wise precaution to have your pet vaccinated.

Feline Pneumonitis.—This disease is sometimes called "cat distemper"—as indeed is feline enteritis—but it has no connection with dog distemper, and is not transmissible to dogs or to human beings. Both mild and severe forms occur, and the incubation period varies from 5 to 8 days. The mild form may seem like a cold, and there is a weeping from the eyes and a varying degree of conjunctivitis. There is a thin, clear discharge from the nose, with a characteristic sneezing. Provided that the animals can be made to continue eating, and are kept in warm and dry but ventilated conditions, recovery may be rapid and not entail serious loss of condition. The eyes should be treated with a suitable preparation, such as silver vitellin. There may be secondary bacterial infection in cases that are neglected.

The severe form of the disease has similar, although more severe, commencing symptoms, but the nasal discharge becomes purulent and there is often profuse salivation, with much spreading of the long ropes of saliva. The cat is listless, dislikes strong light, and seems to resent being disturbed. It loses its appetite, and rapidly becomes thinner over a period of from 2 to 5 days or so. Breathing becomes laboured, and a bronchopneumonia develops. There may be a high death rate in young kittens, and pregnant females may abort. Recovery tends to be slow, and is often complicated by bacterial infection. Some of the modern antibiotics appear to be highly effective in the treatment of many cases of this disease, but they must, of course, be given under veterinary supervision.

Tuberculosis.—The cat, like the dog, can contract tuberculosis, but so far as is known only the bovine form has been known to infect it. The infections usually comes, of course, from milk, and the increase in pasteurisation will tend to reduce the incidence of the disease in cats. The

disease commences in the abdomen, but may spread to the lungs. There is general wasting.

Skin Diseases.—As in the case of the dog, skin disease in the cat is usually of parasitic origin, and fleas and mange mites are again the chief source of trouble in Great Britain. Cats do so much of their own toilet that the average household cat has probably a cleaner skin than its canine counterpart. When skin disease does develop, it is strongly advised that the animal be taken to a veterinary surgeon for appropriate treatment. As a rule cats greatly resent the interference which must accompany any attempt to bathe or dress an affected place, and for this reason it is usually unwise for an owner to attempt to do other than make an inspection. Very small patches of skin eruption may clear satisfactorily if the surrounding hair is clipped away with curved scissors, but generally speaking skin disease calls for professional attention.

Diseases of the Ear.—The outer ear of the cat is frequently affected, and in a great many cases a form of mange mite is responsible. The animal provides evidence of the trouble by scratching and shaking its ear and generally showing its discomfort. It will not always be possible for an owner to make a thorough examination, as in many cases the cat objects, but if it is possible to look inside the ear it will be seen that there is a dirty and usually brownish mess of tissue, sometimes mixed with dried blood or pus. Not all cases are as bad as this, of course, but if a cat persistently worries its ear it should be taken to a veterinary surgeon. There are satisfactory dressings for this condition, and owners will be able to dress their cats if the latter are docile. Otherwise it is necessary to have the ears dressed by a veterinary surgeon or by one of his staff.

A cat's ear is frequently the site of a blood blister, or hæmatoma. This is usually the sequel to a blow, such as a slamming door, and shows itself as a large, tense swelling, which when opened by the surgeon proves to be an accumulation of serum usually tinged with blood. Some cases become infected at the time of injury, some after with the patient's rubbing. With the greatest surgical skill in the world one must expect a slight deformity, and the cat develops a puckered ear, much the same as the human boxer.

Disease of the Bladder.—The bladder is a common seat of disease in cats, and is frequently affected through the blocking of the natural water-passage by small sand-like calculi. Naturally, male cats are more often affected, as the terminal end of the urinary tracts is wider and more dilatable in females. The urine is unable to escape, and the bladder becomes filled with a mixture of urine and the sandy calcular matter. The condition may be diagnosed quite readily, as the cat usually collapses, or partially collapses, and one may easily feel the distended bladder through the walls of the abdomen (belly). It is necessary to send for professional help immediately, and, while no relief can be guaranteed, it is often possible to relieve the condition by judicious manipulation. Owners should not attempt to do this themselves (unless help cannot be obtained), as they may easily burst the bladder. As the animal is usually in a state of collapse when the condition is discovered, it makes a bad risk for actual operation, and relief by *skilled* pressure is usually to be recommended.

Ringworm.—There are two common kinds of ringworm in the cat (a third, which may also infect the dog, is more rare; it is the trichophyton which is usually found on cattle). The first kind is acquired from rats and mice, and is most commonly to be found at the bases of the claws, from where it may spread to the ears and face. The individual lesions are circular and yellow in colour, and consist largely of a scabby material. This kind of ringworm is known as "favus."

The second type of ringworm (microsporon) is more important, because it is more readily transmissible to human beings. Whereas this form usually sets up circular scaly lesions in the dog, it often infects cats without there being much naked-eye evidence of its presence. Indeed, in the cat the condition is often unsuspected until the owner himself becomes infected and consults his doctor.

Ringworm should be treated or dealt with by a veterinary surgeon, who will also confirm or refute by special methods the presence of microsporon in cats

Intestinal Parasites—" Worms."—The cat also is subject to both roundworms and tapeworms. The roundworm which parasitises cats in this country is similar to that of the dog (although a different species) and is also much more harmful to the young than to the adult animal. In kittens the symptoms are a general unthriftiness, staring coat, and in some cases diarrhœa and a "pot-bellied" appearance.

The commonest cat tapeworm in this country is one which passes its intermediate stage in the rat or mouse, or sometimes in other rodents. The tapeworm, which, as mentioned under the section on dogs, is dangerous to man, is sometimes found in the cat also.

Accidents and Injuries.—Despite their sagacity and alertness in many ways, cats seem curiously unable, in many instances, to acquire road-sense. They are dazed by a car's head-lights, while if a motorist sounds his horn they tend to stop still in their tracks.

Injuries from traps, *e.g.*, gin-traps, are very common, and it is probable that many thousands of cats annually are maimed in this fashion. Cats suffer injury from shooting, from stoning, and from blows with sticks. Since they are predatory animals, they have often to pay the penalty inflicted on them by wrathful people. Needless to say, cats which survive to return home usually require expert treatment.

Poisoning may be included under this heading. Although there are doubtless many deliberate attempts to poison marauding cats, alleged "poisoning" is often no more than a case of feline enteritis, and owners should not claim glibly that their cats have been poisoned until they have expert evidence to back their judgment.

Fur-balling, as it has been termed, may be mentioned here. Cats, especially the long-haired varieties, must often ingest hair during their toilet, and occasionally serious trouble (a stoppage of the bowels) is brought about by a mass of such hair which has collected in a part of the bowel. There is constipation, loss of condition, and often evidence of considerable pain. Such cats should be taken to a veterinary surgeon.

Bites and scratches are even more common in the cat than they are in the dog, and subsequent sepsis is equally likely.

FERRETS.

Description.—The ferret is probably a domesticated form of the pole-cat (*Mustela putorius*), and is known sometimes by that name and sometimes as *Mustela furo*. Most tame ferrets have pink eyes and yellowish-white fur, but there are darker forms believed to have resulted from crossing in previous generations with wild pole-cats. Indeed, these darker forms are popularly termed "pole-cat ferrets." They are of two main kinds, the first having creamy under fur and black guard hairs, and the second being a chocolate-brown colour, with brown upper parts and black under parts, and a few scattered light hairs on the face.

Ferrets are long creatures in relation to their body weight, and when fully-grown may have a body 14 in. long or more and a tail of 5 in. Some strains grow appreciably larger. The main use of the ferret is, of course, in rabbiting, for which purpose they have been employed for many centuries. Although they can become fierce if not accustomed to regular handling or kind treatment, and are capable of inflicting a nasty bite, they may nevertheless be made into docile and highly intelligent pets. It is most important to win their confidence from the beginning and to accustom them to regular handling from the time they are young "kittens."

Accommodation.—Ferrets must have dry, clean accommodation in a room free from draughts but well ventilated. Wood is warmer than metal, but more difficult to clean, and is best lined with hard asbestos sheeting, which is resistant to water. The most suitable accommodation comprises a sleeping compartment of similar proportions to a small kennel, leading by a small doorway or "pop-hole" to a wire-netting exercising run, which should be as large as possible compatible with cleanliness. It is a good idea to have a means of closing the doorway so that the ferret or ferrets may be confined within the sleeping-compartment if necessary. Wood-wool makes an excellent bedding, but if difficult to obtain newspaper may be provided for the ferret to lie on. The floor of the run may have a false bottom or may be sprinkled with sawdust. It is imperative to keep the whole of the accommodation clean and dry, not only to avoid smell but also to prevent the ferrets from developing a very serious necrotic infection of the feet known as "foot-rot."

Feeding.—Many ferrets are unfortunately not fed adequately. It must be appreciated that basically they are carnivorous animals, and that their food requirements are more similar to those of the dog and cat than those of rodents. Indeed, many of the general remarks made about the principles of feeding dogs and cats apply to ferrets also.

Most ferrets like bread-and-milk, and while this is an excellent article of diet, it is in itself inadequate. Up to about 4 oz. of raw meat (minced for younger animals) daily is an excellent basis, and this may be replaced by fish. Liver, especially raw liver, is an excellent source of many factors, and there is good reason to provide some at least weekly if it can be obtained. Failing this, it is advisable to add 1–2 per cent. of whole dry liver to the diet. Once ferrets are grown, one feeding daily—at a fixed time—is sufficient. The female (jill) should have ample supplies of milk just prior to the birth of her young and while she is suckling them.

Breeding.—In the northern hemisphere the female ferret usually comes into œstrus (season) in early March of the year following that in which it is born. If the jill does not conceive during this œstrus she will have a further œstral period in July or August The desire of the jill to mate is very strong, and if not allowed to do so, some animals sometimes have been found to waste and pine. The act of mating is prefaced by very vigorous behaviour on the part of the male (hob), and anyone not appreciating the performance might think that he was out to kill his mate! The mating act itself is usually prolonged, and may take up to three hours. If left together the hob and jill will probably mate from two to four times during the course of a couple of days. As in the cat and rabbit, ovulation or the shedding of the egg from the ovary takes place as a result of mating, and not spontaneously. The period of gestation is forty-two days, and the numbers of young born usually varies from five to thirteen, the average litter being six to eight. Pseudopregancy occurs if the jill is not mated, and may become outwardly obvious as in the case of certain bitches.

Males also have a seasonal rhythm, their capacity to fertilise being greatest from early March to August. Young hobs seem to be active about a month earlier than older ones. The length of daylight or, rather, the incrementation in light from day to day, has an important bearing on breeding capacity in both sexes, and by the use of artificial light it has proved possible to induce either œstrus or male activity at different times of the year.

The young are hairless and blind, and weigh on the average under ½ oz. at birth. Their eyes open at about four weeks, and they can then commence to eat small pieces of solid food to supplement their mother's milk. They may be weaned at from six to eight weeks.

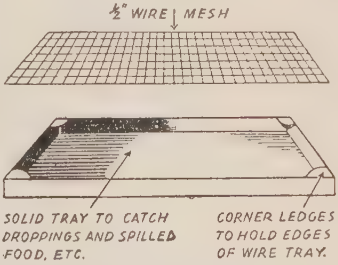
Diseases.—The most serious disease of ferrets is *canine distemper*, and the variant known as "hard pad" (see under dog) is equally capable of infecting ferrets. Such infections can wipe out entire stocks, and every care should be taken to prevent their spread from dogs to ferrets—and vice versa. A veterinary surgeon should be consulted immediately when a ferret becomes ill or out of sorts. Ferrets are also susceptible to some strains of *human* influenza, and should not be tended by persons with colds or with any indications of "flu." The feeding of infected milk may give rise to *tuberculosis*, and as a safety measure it is better to give only tuberculin-tested or pasteurised milk, or milk that has been boiled to destroy infection. *Foot-rot* has already been mentioned, and must on no account be neglected. *Mange* or "scabies" of the back and tail region should be dealt with promptly, employing modern preparations. Abscesses of the neck region are often encountered, and should receive professional treatment if they do not clear up rapidly, for they may spread with dire consequences.

RATS.

Description.—Tame rats are domesticated varieties of the wild Norway or "brown" rat (*Rattus norvegicus*). Such rats are usually albinos or black-and-white, although other colours have been bred. The hooded varieties are those in which the head and foreparts are mainly black or chocolate and the remainder of the body, apart from small patches the same colours as the hood, is white. Tame rats differ materially from wild ones in disposition, and properly managed are extremely tractable. Healthy specimens accustomed to handling bite only when frightened, *e.g.*, when a sudden movement is made in front of them. Males appear to live longer than females, but three years is a good age.

"Black" rats, *i.e.*, the species (*Rattus rattus*) sometimes known as the ship or Alexandrine rat, have been bred in captivity, but tame strains are not generally available.

Housing.—Tame rats require a warm, even temperature—65–70° F. all the year round—and draughts or lowered temperature may precipitate lung diseas eor other disorders. It is best to have a complete spare set of boxes or cages, and to change to fresh quarters weekly except when the females have unweaned young with them. Empty cages should be cleaned and disinfected thoroughly before being used again. Provided the temperature conditions are suitable—and this is essential—metal cages of the types employed in scientific laboratories are best, with wire-mesh false bottoms and trays containing sawdust to catch the droppings. Accommodation should be



ample, and even for a pair of pet rats the cage should measure about 30 in. × 18 in. × 18 in. If wooden boxes are employed it may be desirable to line them with hard asbestos sheeting or galvanised metal to prevent damage from gnawing.

Small, dark "shelters" and exercising devices, *e.g.*, wheels or ladders, are appreciated by the rats, but must be kept clean. Wood-wool makes the best bedding.

Feeding.—Rats may take a wide variety of foods, including many of our own, and there are

several successful ways of feeding them, including the provision of specially formulated "rat-cubes," of the same type as that described below for mice. A good daily diet is wholemeal bread, mixed cereals (*e.g.*, oats, wheat, hempseed), with about

WATER BULB SUITABLE FOR USE WITH PET RODENTS

5 per cent. dried brewers' yeast and milk either fed separately or mixed with the rest of the food. Twice weekly each rat should be given up to ½ oz. or more of meat, liver, fish, or other "animal protein." A little fresh greenfood (even grass) is appreciated, and in winter especially some supplement containing vitamins A and D is desirable. Expectant and nursing mothers should have as much milk as they require. Never overfeed or allow uneaten food residues to remain in the cage. Fresh water (preferably in bulbs or bottles) should be available at all times. Far cleaner than open dishes are the special but simple type of water bulbs suspended on or in front of the cage or box so that the rat can drink from the rounded end of the spout. A simple substitute is a medicine "flat" bottle—or even a ¼- or ½-pint milk-type bottle. This should be fitted with a cork—or, better, a rubber bung—pierced for a piece of bent glass tubing. Provided that the free end of the glass tubing is not sharp, and is chosen so that the aperture is considerably smaller than that of the tube itself, the water will not run out unless sucked out by the rat. The spout should, of course, be within easy access of the rat, which will soon learn to drink from it.

Breeding.—Rats can breed at quite a young age (usually being capable of mating when fifty to sixty days old), but it is better to separate the sexes within a fortnight or so of weaning (weaning being usually at twenty-one days of age) and to mate at about 100 to 120 days of age onwards. the female rat has an œstrous cycle lasting just over four days. One male (buck) may be mated to one female (doe)—this is probably best in the case of pet rats—or with two or three females if preferred, but it is unwise to keep more than one adult male in the presence of females. The gestation period is twenty-one to twenty-two days or occasionally a few days longer. The number born varies considerably, but often it is best to try to rear only six to eight young. The young have their ears open at 2½ to 3½ days, cut their incisor teeth at eight to ten days, can find their way to their mother at about the same time, open their eyes at fourteen to seventeen days, and may leave the nest at twenty-one days. In the case of pet rats it is probably best to leave the young with the mother for up to a week or so longer. Breeding can occur all the year round, but takes place less readily in winter.

Handling.—Rats should not be "tailed," or the skin may slough off. Regular handling after weaning is excellent and promotes docility. The weight of the body should be supported.

Diseases.—On the whole rats are much less liable to disease than mice, provided temperature conditions are suitable. The commonest infection is *broncho-pneumonia*, often precipitated through draughts or cold. *Mange* (especially of the ear) and infestation with *lice* may occur, and should be dealt with promptly by means of modern insecticides. Avoid contact with wild rodents, or the use of food or bedding that may have been contaminated by wild rats and mice.

MICE.

Description.—Tame mice are descended from the common house mouse (*Mus musculus*), and it is believed that mice have been domesticated for over 3,000 years. Apart from albino or "white mice," there are many varieties that have been bred by the extensive "mouse fancy," and there is a wide range of coat colour and also different types of coat, *e.g.*, long-haired, short-haired, and rex. "Waltzing mice" have an abnormality of that part of the inner ear concerned with balance. Mice may live up to thirty months, and in exceptional cases attain the age of three years or more.

Housing.—Although strains vary, most tame mice require a warm even temperature and the same general remarks concerning temperature range, bedding, and wooden or metal cages apply as in the case of rats. If a solid floor is used, this should be covered with clean sawdust. It is a good plan to change to a clean cage regularly, except when the female (doe) is nursing her young. If the cage is large (as in the case of pet mice it should be, with a floor space of say 24 in. × 12 in. × 12 in. for a group of mice), inner nest-boxes should be provided—one for each doe if breeding is taking place, although two does will often share the same nest-box. (In changing to fresh cages the nest-box, with mother and young inside, may, of course, be moved over.) A "two-storey" cage, with a ladder or "staircase" to the upper part, is an attractive variation, although difficult to keep clean. Mice should be kept well out of reach of wild rodents, from which they may all too readily contract disease.

Feeding.—Mice have not quite such a wide dietary range as rats, but there are several different ways of feeding them, including the provision of special "mouse cubes." These mouse cubes are of varying composition. One of the most successful, devised by workers in the Medical Research Council's laboratories, is known as "Diet 41," and is made up of the following parts by weight: wholemeal flour, 45; Sussex ground oats, 40; fish meal, 8; dried yeast, 1; dried skimmed milk, 3; cod-liver oil, 1; and common salt, 1. Diet 41 has also been employed for rats and monkeys, although for the latter particularly it requires supplementing. It is perhaps worth emphasising that cod-liver oil must not be fed in excess (½% of the diet is quite sufficient, and should not be exceeded), or it may prevent breeding and possibly have other harmful effects. Cubed diets are best fed from a wire basket through which the mice enjoy gnawing and eventually pulling out the pieces. Wholemeal bread is excellent if not allowed to become stale, but it should not form the sole article of diet, and it is a good idea to feed it alternately with a grain mixture (made up of rolled oats, wheat and other cereal grains, or mixed bird seed). Up to about 5 per cent. dried brewers' yeast is excellent, and so is fresh or dried milk, especially for mothers that are carrying or nursing young. Cheese is relished, but may smell if not fed carefully. Mice sometimes like an occasional pinch of marmalade, and it is a good idea to provide lettuce or other greenfood every week or so. There should be a constant supply of fresh water, preferably from bulbs or bottles as described for rats.

Breeding.—Young mice may be weaned at twenty-one days, although it is usually preferable to leave them with their mother for a further week. The age at which mice are capable of mating varies considerably from one strain or individual to another, and while the average is six to eight weeks, it may be much younger. It is therefore desirable to separate the males from the females at or shortly after weaning.

Mice may be mated up at two to three months of age, and the best arrangements are one male (buck) to one or two females. A pair of mice or a "bigynous trio" makes a successful combination. The œstrus cycle is similar to that of the rat, but its length appears to vary with coat colour, being longest in the brown mice and shortest in blacks and albinos. The gestation period is usually from eighteen to twenty days, but may be prolonged if the female was still suckling her previous litter when she conceived. There may be up to twelve or more young in a litter, but the average litter size is from five to seven. The second litter is usually the largest, and subsequent litters tend to decrease in numbers, so that the sixth is usually smaller than the first. Breeding may take place all the year round, although, as with rats, fertility is higher during the summer months.

Handling.—Any rapid or rough movement may frighten mice and cause them to bite through fear. Mice should be lifted by the tail—not too near the tip—and may be held in the palm of the hand, where they may be suitably restrained by keeping the tail between two fingers.

Diseases.—Mice are unfortunately prone to many diseases, although the risks will be much lower if they are kept in suitable surroundings, great care is taken to avoid infection, scrupulous cleanliness is observed, and the standard of feeding is good. One common source of infection is the presence of the excreta of wild rodents on bedding or foodstuffs. A common disease is that sometimes called "*mouse typhoid*," caused by organisms of the Salmonella group. Although some mice recover, they may remain carriers of infection, and once this disease is diagnosed it is best to destroy the affected mice and those in contact with them, and not to employ any of the cages or utensils for fresh mice without adequate sterilisation. There are other septicæmia diseases of mice, and also virus diseases, including certain types of *pneumonia* and a condition known as *infectious ectromelia*. The accurate diagnosis of these calls for expert opinion and often for special bacteriological or other examinations. The mouse-owner should, however, be able to recognise signs of ill-health or departure from normal, one of the commonest being loss of appetite. In young mice the coat should be smooth and glossy. As mice get older there may be loss of pigmentation (in coloured mice) or even loss of fur. A sick mouse usually sits hunched up and has a ruffled coat, while the eyes may be partially closed or have some discharge. A healthy mouse will usually catch on to suitable objects when held by its tail and is capable of pulling quite hard, whereas the pull of a sick mouse is much weaker. If one or more mice die it is best to destroy at once any cage-mates that appear seedy. As in the case of rats, external parasites should be dealt with promptly with the aid of modern insecticidal preparations.

GOLDEN HAMSTERS.

Description.—There are many species of hamsters in the world, and more than one kind can now be bred in captivity. The one referred to, however, is the Golden Hamster (*Mesocricetus auratus*), a delightful little creature of which a full-grown female (females are larger than males) rarely exceeds 7 in. in length. This history of the domestication of the golden hamster is quite remarkable, for prior to 1930 only museum specimens were known. In that year a mother and her twelve young were dug up in a field near Aleppo and were taken to the Hebrew University, Jerusalem, and from that one family have been bred the hundreds of thousands of golden hamsters now employed as pets or as laboratory animals in many parts of the world. The species has taken well to captivity and, although capable of inflicting a nasty little bite if frightened or handled roughly, becomes docile and friendly when properly cared for. Characteristic features are the soft, smooth fur, the large black eyes, the "cheek pouches" in which food is stored and which may become enormously distended after a meal, the short, stumpy tail, and the extremely loose skin, inside which the hamster can turn round to a considerable degree.

Housing.—The same remarks about accommodation, environmental temperature, freedom from draughts, fittings, and other general considerations (including cleanliness) apply as in the case of rats and mice. For breeding purposes a dark inner chamber or nest-box is desirable. Several hamsters may be kept together, but the introduction of a stranger (or even the re-introduction of a former cage-mate that has been removed for some time) may lead to fighting.

Feeding.—Satisfactory diets include the following: (1) rat cubes (*e.g.*, "Diet 41"), carrots, greenfood, and milk; (2) cereal grains and/or wholemeal bread, carrots, greenfood, and milk; (3) steamed Rangoon beans, wheat, maize meal bread, a little Marmite, and milk. Care must be taken not to allow storage of excess food, which will deteriorate and cause a smell. Grass is a suitable source of greenfood during its growing season. Apples and other fruits are often relished. Water, preferably in bulbs or bottles as described for rats, should always be available.

Breeding.—Golden Hamsters attain puberty at from ten to fifteen weeks of age, or even younger, males being usually earlier. Generally speaking, it is best to defer breeding until after fifteen weeks of age. There is an œstrus cycle of about four days, and the gestation period is very short, averaging sixteen days, although sometimes up to nineteen days. Mating not followed by conception results in phantom or pseudopregnancy. Litter size varies from one to fifteen, but the average is six to seven. Not many females have more than four litters and although both sexes may live up to two years, breeding by the female is rare after nine months. The young are naked and blind at birth. Hair first appears at five days, and covers the whole body at eight days. The eyes open at about eleven days, and soon after this the young begin to take food for themselves and may be weaned at three to four weeks. Care must be taken that the female does not injure the male, and for safety's sake it is probably better to keep only one female and one male together and to remove the male before the young are born.

Handling.—Gentleness is essential, and sudden movements should be avoided. The tail is much too short to use, and the easiest way is to lift them by the loose skin over the back and shoulders. As already noted, they can twist easily within their skins, unless a substantial amount is taken in the hand. After picking up they may be allowed to sit on the palm of the hand.

Diseases.—Several diseases of hamsters are now known, and, like most rodents, they are susceptible to *Salmonellosis* (see notes under "mouse typhoid" and "paratyphoid" in guinea-pigs). One of the most prevalent conditions is *ear mange*, in severe cases of which the condition spreads from the ears to other parts of the body. Modern anti-mange preparations are highly effective.

CAVIES (GUINEA-PIGS).

Description.—Cavies or guinea-pigs (*Cavia porcellus*) are rodents, and are descended from one or more of the several kinds of wild cavy found in South America. They are believed to have been domesticated by the Incas long before Europeans "discovered" that part of the world. They make excellent pets, but are easily frightened, and should be treated gently and quietly. They usually behave quietly, although there may be fighting between adult males ("boars"), while the arrival of food—or the entry of a person into a room, which fact is obviously connected with feeding-time—usually sets up a chorus of chirrup-

ing squeaks. There is to-day a considerable cavy "fancy" in Great Britain and other countries, and many varieties are recognised, including rough-coated and smooth-coated types. Among recognised colours are the agouti (banded hairs), brindle, cinnamon, tortoiseshell (tricoloured), and Himalayan (white with attractive black points). The long-haired Peruvian and rosette-haired Abyssinian breeds are popular. Guinea-pigs may live up to two to three years. There is a small tail (composed of from five to seven caudal vertebræ), but usually this is so short that it does not project outside the body. There are four toes on each of the fore-feet and three on each hind foot. An adult guinea-pig may measure up to 10 in. or more in length, and sometimes its weight is well over 2 lb.

Housing.—Guinea-pigs may be kept outside or inside. If outside conditions are favoured, great care must be taken to protect them from dogs, cats, and rats. The last-named may be a danger also in conveying disease. The run should be in a sheltered position away from wind and direct summer sunlight. Tent-shaped waterproof shelters, with wooden floors covered by cleaning trays, have been found satisfactory. Another method is to keep them in hutches of the same type employed for rabbits and when conditions are suitable to let them out into a temporary run on the lawn surrounded by ½ in.-mesh wire-netting that is at least 12 in. high. (N.B. This will keep dogs or cats out.) Guinea-pigs will crop the grass and help to keep the lawn smooth. Great care should be taken not to allow the ground or floor to become so contaminated by guinea-pig excreta that it conveys disease from one animal to another.

If indoor methods are selected, an even, preferably warm temperature is desirable, and there should be freedom from draughts. Guinea-pigs have been found to thrive best at about 65° F. with a humidity range of 45–55 per cent. Provided warm conditions are available, metal cages are easier to keep clean than wooden ones, while a false bottom of wire mesh, above the cleaning tray, is helpful. Wood-wool is again the best bedding. Cages must not be too small, and a pair of pet guinea-pigs should have about 14 sq. ft. of floor space. It is a sound principle, as with rats and mice, to change frequently to a clean cage, the used one being cleaned and disinfected thoroughly before being used again.

Feeding.—Guinea-pigs, like human beings, apes, and monkeys, require a source of vitamin C (ascorbic acid). Normally they obtain this from greenfood, but in winter especially they may not secure enough in this way. The daily requirement of an adult guinea-pig is about 2 milligrammes, and supplies can be obtained from a chemist's shop.

There are many different methods of feeding guinea-pigs. Among cubed or pelleted diets is that known as "Diet 18," which is employed also for rabbits. It contains the following parts by weight: wheat feed, 15; grass meal, 30; decorticated groundnut meal, 15; linseed cake, 10; barley meal, 20; common salt, 1; and chalk, 1. This is fed together with fresh greenfood to supply vitamin C. For feeding without the use of compressed diets a good plan is to provide a daily "concentrate ration" of about 1 oz. per head of a mixture of 2 parts bran and 1 part crushed oats, and to feed in addition ample amounts of cabbage, lettuce or other greenfood, meadow hay of good quality, grass, and raw vegetables. Although guinea-pigs normally derive moisture from fresh greenfood, and may appear to take little or no water for long periods, it is a mistake not to provide a fresh supply, preferably from water bulbs, or from inverted bottles fitted with a stopper and drinking-spout. A little dried brewers' yeast makes an excellent addition to the diet, while for females ("sows") when pregnant or lactating milk is excellent. Dead foliage should be removed from greenfood, and soil and dirt cleaned off. Frosted greenfood should be soaked in warm water before it is given to guinea-pigs. Unfortunately, hay may be contaminated by wild rodents, but it forms an excellent article of diet. Never allow food residues to remain in the cage.

Breeding.—The lactation period of the guinea-pig is a short one. The gestation period averages sixty-three to seventy-five days, although variations of fifty-eight to seventy-two days are known, and the young are born in an advanced state, with their eyes already open. They can run freely with their mother shortly after birth. They are able to nibble a little food as early as the second day, and by the time they are two to three weeks old they are completely independent and are neglected by their mother. A sow will often mate again the day the young are born, or shortly after, so that a rapid succession of litters often occurs.

Guinea-pigs are capable of mating from about fifty-five to seventy days of age, or even younger in certain circumstances, which include the provision of a high plane of nutrition. The œstrous cycle averages fifteen to seventeen days, although it may vary from thirteen to twenty-five days. The actual period during which mating may occur usually lasts only from about six to eleven hours. One boar may run with as many as twenty sows if so desired, but in the case of pets it is much more interesting to run a boar with only one sow, in which case she need not usually be removed to a separate cage before the young are born. The young guinea-pigs should be separated from the older ones shortly after weaning, and the sexes separated at four to five weeks of age if they are not to breed prematurely. It is better to wait until the animals are approaching six months of age or so before they are mated, for they do not become fully grown and "filled out" until they are between six and nine months.

Handling.—Guinea-pigs are timid creatures, and should be handled gently. They are best picked up with both hands. If a guinea-pig is to be held in order to examine it for any purpose, a good method is to place one hand over the animal's shoulders, with the fingers and thumb around its neck, and to extend its hind limbs with the other hand.

Diseases.—The most important infectious disease of guinea-pigs is, like "mouse typhoid," caused by organisms of the Salmonella group, and it may be contracted from wild rodents or from food or bedding contaminated by them. In guinea-pigs the disease is known usually as "*paratyphoid*" (or sometimes as "*salmonellosis*") and it may take an acute form, causing death within a few days, or a more chronic form in which many animals recover to become symptomless carriers of disease. Outwardly healthy, they may infect susceptible guinea-pigs with which they are placed. Cold or other environmental variations, and faulty feeding, can help to set off an outbreak, for there are few stocks in which the organisms are not lurking in some "latent carriers." *Coccidiosis* is common, but is a much less serious threat than in the case of rabbits. It has been set up in infected stocks by feeding inadequate diets, and provided that nutrition and hygiene are adequate there is rarely serious trouble from this disease. *Infections of the respiratory tract* may occur, but are uncommon except when there is overcrowding, high humidity, or damp bedding. Sometimes organisms of the Pneumococcus group cause not only disease of the respiratory tract but also a generalised infection of the serious membranes of the body. When this disease occurs it may produce death without much warning. It is possible that the infection sometimes comes from human beings. The disease known as *pseudotuberculosis*, and described under rabbits, occurs in guinea-pigs also. Again, environmental conditions and faulty feeding may predispose towards active infection.

With good fortune and sound management, trouble from these serious infections may never occur. *External parasites* should be dealt with promptly by modern methods. Sometimes *non-parasitic skin disorders* occur when the diet is faulty, *e.g.*, too dry or lacking in sufficient fresh greenfood of good quality.

RABBITS.

Description.—Domesticated varieties of the wild European rabbit (*Oryctolagus cuniculus*) are now kept in many countries of the world. The wild rabbit is believed to have been introduced into Great Britain about the twelfth century A.D., and to-day it is a serious pest of agricultural land and forestry schemes. Tame rabbits have been bred for centuries, and some of the breeds and strains that have been produced differ appreciably in size, colour, and habits from the common wild form. Some breeds have been specially bred for table purposes, while others (*e.g.*, the Angora, Sitka, and Argente de Champagne) have been developed for their fur. In addition, many varieties are produced for show purposes by the extensive rabbit "fancy." The small hardy Dutch rabbit (usually black and white) is one of the kinds suitable for beginners. Among well-known categories are the English, Japanese, Himalayan, Belgian Hare (really a rabbit), Flemish Giant, Beveren, Blue Imperial, Polish, Havana, Lop, Half-Lop, Chinchilla, and New Zealand White. The Copenhagen rabbit appears to be identical with the New Zealand White. The smaller breeds weigh only 4–6 lb. when fully grown, whereas some specimens of some of the giant breeds attain a weight of 20 lb. or more.

Rabbits and hares were formerly classified with the rodents, but to-day they are placed in a separate Order of mammals, known as the Lagomorphs. Young rabbits (in contrast to leverets or young hares) are blind and helpless for some time after birth. Tame specimens may live for four to five years, and individuals have lived for up to thirteen years.

Since rabbits are employed for commercial purposes, various systems of management have been devised, including the use of movable ark-huts, with covered runs, that can be moved regularly to fresh ground. If kept indoors rabbits do not need special heating, but freedom from draughts, damp, excessive cold, and access by wild rodents is most desirable. A garage is regarded as an unsuitable place, owing to the susceptibility of rabbits to exhaust or engine fumes. One of the great difficulties of rabbit-keeping is coccidiosis, which is a serious disease in rabbits and hares. (European hares could never be bred successfully in captivity until means of overcoming coccidiosis were discovered.) With young rabbits especially (*i.e.*, those that have left the nest and are able to run about freely) it is a sound principle to move them to a clean floor or fresh ground every two days, so as to "break" the life-cycle of the coccidial parasite. One way of doing this is to have "back-to-back" cages or hutches, from one to the other of which the rabbits may be transferred easily. The empty cage or hutch may then be cleaned and disinfected thoroughly and allowed to dry out before the rabbits are returned to it. Wood-wool makes a suitable bedding material, although the female (doe) will pluck her own fur to line the nest when her litter is due to be born. Wire-mesh floors with a tray beneath are convenient, but if solid floors are used these should be sprinkled with fresh sawdust daily or every other day. Provided the standard of hygiene can be maintained, cages or hutches and their runs should be large. The absolute minimum is "1 sq. ft. of floor space for each 1 lb. weight of adult rabbit," *i.e.*, if there are two rabbits totalling 12 lb. in weight there must be at least 12 sq. ft. of floor space. If cages or hutches are stacked one on top of the other the lowest should be well clear of the ground, and if there is only one hutch this, for convenience and safety from wild rodents, should be 2–3 ft. off the floor.

Feeding.—The wild rabbit grazes at dusk and dawn, and it is preferable to feed tame rabbits twice daily, while pregnant or lactating does and young rabbits benefit from three meals a day. As in the case of guinea-pigs, the ration may be thought of as consisting of two parts, a concentrate portion and a portion consisting of greenfood and other succulent material. The concentrate portion consists usually of a mixture of cereal grains or of some other form of mash. Successful mashes, of which there are many, include: (1) a mixture of 4 parts cereal grains and 1 part dairy cake; (2) equal parts of bran, weatings, flaked maize—or barley meal—and fish meal. This second is useful for breeding. If materials for the mash are in short supply they may in part be replaced by cooked potatoes. An average daily food allowance for a resting (non-breeding) adult of medium size would be: greenfood (grass, clover, weeds, lettuce, etc.) and/or roots, 12–16 oz.; hay (good quality), 2–3 oz.; and concentrates (cereal grain or meal mash), 2 oz. If cooked potatoes are used they should be fed at the rate of 4 parts to each 1 part of cereal that they replace. For a doe nursing her litter a suitable diet would comprise: greenfood to appetite, hay (good quality and preferably containing clover or other legume), 2–4 oz.; concentrates (preferably with fish meal or some other suitable source of "animal protein"), 4–6 oz.; and common salt at the level of up to 1 per cent. of the ration. A mineral mixture is preferable to salt alone. Excessive greenfood, especially in the form of cabbage and other Brassica plants, may cause polyuria, *i.e.*, the passage of excessive quantities of urine. No matter how much fresh greenfood rabbits may have available, a supply of fresh water should always be provided. The daily water requirement of the rabbit is quite high, and certain bad habits such as urine drinking or even cannibalism may result from an inadequate intake of water. Pots that cannot be overturned or, preferably, water bulbs or bottles as described for guinea-pigs, are the most suitable means of providing water.

"Diet 18," described under guinea-pigs, is one of several types of compressed diet successfully employed for rabbits. Fresh greenfood is preferably fed in addition, while the water requirement with diets of this kind is considerable.

Breeding.—The age of puberty varies with the breed, and also with the time of year at which the individual rabbit was born. Rabbits born in spring are usually capable of breeding at a younger age than those born in the autumn. In Great Britain the wild rabbit has a fairly sharply defined main breeding season, lasting from January to June, but some degree of "out-of-season" breeding may take place at almost all other times. Tame rabbits may not breed freely during the winter months, especially if environmental conditions are cold. Mating may take place as early as four months of age, and although this does not often result in pregnancy, it is accompanied by competition and fighting between individuals of the same sex. Males (bucks) and females should therefore be separated at weaning, or at least before they are four months old. Fertile matings may occur at from about 5½ months of age onwards, but it is wise to defer breeding until later—say seven to eight months for most breeds. The female does not ovulate or shed her eggs from the ovary spontaneously as do most domestic mammals, but, like the cat and ferret, does so in response to the act of mating or some other strong stimulus. Even playing between two does may precipitate ovulation, in which case a so-called "phantom pregnancy" (pseudopregnancy) may result, the doe that has ovulated appearing pregnant and even developing lactating mammary glands. There is not therefore an obvious regularly recurring œstrus cycle as in the domestic rat, mouse, and guinea-pig, and in summer at least the doe may be ready to mate at almost any time. Observation suggests, however, that there are fluctuations in the desire to mate. The act of mating in rabbits sometimes causes alarm that all is not well to those that have not hitherto witnessed it, for the buck usually emits a peculiar cry and loses his balance to fall over sideways. It is usually best to separate the buck from the doe before the young are born. The gestation period is usually thirty to thirty-two days. In wild rabbits a high percentage of embryos die and are "resorbed," and are therefore never born. In some populations it appears that about two-thirds of all rabbits conceived (including about 60 per cent. of total litters) are lost before birth in this way. Losses from this cause are probably much less common in domesticated rabbits, especially when the standards of feeding and management are high. Litter size is variable, and depends in part on the breed or strain. In some strains mean litter sizes up to eight or nine have

been obtained, but a mean of four or so is more common. Does that do not prepare the nest or rear their young properly should not be selected for further breeding. The doe with her new-born litter should not be disturbed unduly, or she may desert her young, which are blind and helpless at birth and are entirely dependent on her for at least three weeks, after which they begin to nibble food to supplement the milk that they receive from her. The eyes open at about fourteen days. Weaning should be carried out at between six and eight weeks of age, by which time the young should be able to fend for themselves completely.

Handling.—Rabbits should never be lifted by the ears alone. One good way of lifting them is to grip the ears firmly but gently with one hand and to place the other hand under the rump to take the weight of the rabbit's body. Alternatively, one hand may be placed flat under the rabbit's belly, but this requires more care, and may be a risky procedure with pregnant does. Another convenient way to handle rabbits, especially young ones, is to lift them by the loose skin over the shoulders. Rabbits can inflict quite nasty scratches with the nails of the hind feet. It is incidentally a good plan to examine the nails of all four feet and to trim them if they are too long. A stout pair of scissors, or preferably a pair of clippers, is used, and care should be taken not to cut back as far as the "quick," *i.e.*, the bluish portion at the base of the nail that contains blood vessels and will bleed freely if damaged.

Diseases.—As already indicated, *coccidiosis* is a highly important disease of young rabbits. It may be either of the "hepatic type," affecting principally the liver, or the "intestinal type," affecting principally the gut. Even in the case of the hepatic type, however, the coccidial parasites are picked up by mouth and after penetrating the intestinal walls make their way via the blood-stream to the liver. Hygienic measures are the best means of preventing the disease (see under Housing), but should it break out, prompt treatment with certain sulphonamides or other anti-coccidial drugs may prove effective. In certain rabbitries in which coccidiosis is a constant problem, protection has been obtained by feeding a dilute solution of one of the soluble sulphonamides in place of drinking-water. There are certain types of digestive disturbance that may resemble coccidiosis, and one of these, the cause of which has not yet been established with certainty, is known as *mucoid enteritis*. Some such cases are probably variations of "*bloat*" ("the blows") a condition the cause of which is again not fully established, although there may in fact be several factors. A rabbit may, of course, "blow" after eating fermentative food, but cases of "bloat" can occur independently of this, and some may be due to a virus. "*Snuffles*" is characterised by a nasal discharge, and is not always associated with the same organism. In its milder forms it is not a severe disease, but with the more chronic forms the nasal discharge becomes marked and gives rise to a typical snuffling noise. Severe chronic cases become progressively worse and die of a terminal pneumonia. There is also a severe acute form, in which the rabbit dies so rapidly that the condition is sometimes not recognised. Acute cases that are treated in time with certain sulphonamides may respond well, but chronic snufflers are difficult to treat and go on spreading the infection, and hence are better destroyed. Correct environmental conditions are a great help in preventing this disease. A chronic type of infection is known as *pseudotuberculosis*, which is usually acquired from eating material contaminated by wild rodents or by other infected rabbits. It is caused by quite a different organism from that of true tuberculosis, which is much rarer in rabbits. Clinical cases should be killed, and prevention lies in hygienic measures. Infected wounds or skin abscesses may lead to a disease caused by the "necrosis bacillus" (*Fusiformis necrophorus*) and known sometimes as *necrobacillosis*. It is usually characterised by subcutaneous swellings distributed irregularly over the head and body. Although in the early stages the affected rabbit may remain in apparently good health, the spread of the disease is insidious and usually fatal, and in most instances it is kinder and safer to destroy a case before it progresses too far. There are unfortunately several other infectious conditions occurring in rabbits, but all call for expert help in diagnosis and treatment. Generally speaking, it is a bad policy not to cull an ailing rabbit immediately, and one that is ill should certainly be isolated at once and not fed or tended before the person looking after it touches the healthy rabbits.

Among non-infectious conditions *pregnancy toxæmia* is not uncommon in does during the very late pregnancy, and usually proves fatal within two to three days. It is a "metabolic disorder," *i.e.*, it is associated with some functional derangement of the endocrine or ductless glands or with the inability to control properly the utilisation of its food. Faulty feeding is probably a contributory cause. Diseases of the *heart and blood* may arise occasionally, and can be aggravated by faulty feeding.

Among external parasites, *ringworm* is not common, but may be acquired from rodents. Affected rabbits that are to be treated must be isolated. *Ear mange* (known usually as *ear canker*) is common, and may be treated by strict attention to hygiene, with thorough disinfection of the hut or cage, and by dressing with a modern anti-mange preparation. *Body mange* is much less common but far more difficult to treat.

Among internal parasites, so-called "*bladder worms*," *i.e.*, the larval stages of two dog tapeworms (*Taenia pisiformis* and *Taenia serialis*) are quite common, although rarely fatal. The feeding of grass or other greenstuff to which dogs have had access should be avoided, as well as the contamination of the drinking-water with dog fæces.

Domestic rabbits are susceptible to myxomatosis (*See* "General Information"), and it is a wise precaution to have them vaccinated. The vaccine is inexpensive, and may be obtained through veterinary surgeons and pharmacists.

HEDGEHOGS.

Description.—The European hedgehog (*Erinaceus europaceus*), found throughout Great Britain, belongs to the Order Insectivora, of which moles and shrews are also members. Its diet is, however, by no means restricted to insects, although in nature a considerable portion is probably made up of small invertebrates. There is a good deal of prejudice against them as pets, owing to the fact that freshly caught specimens are usually infested with fleas or other external parasites. The spines of the hedgehog, being well-spaced, make the presence of external parasites more obvious than is the case in animals with a coat of close fur. The hedgehog's spines form its defence, and its capacity to roll up into a prickly ball at the threat of danger is well known. This defence reaction is unfortunately of no avail to it when the danger is an oncoming car or lorry, and thousands of hedgehogs die every years as a result of being killed by vehicles on the roads. Many other species of mammals wander on to the roads, but most attempt to flee when they sense the approach of a vehicle. The capacity to roll up is not secure defence even against animal enemies. There are some foxes, dogs, and cats that have learned to "uncurl" a hedgehog, and subsequently eat it.

Provided that care is taken, a hedgehog makes an excellent pet, especially if given a suitable enclosure in the garden. For a variable time during winter hedgehogs hibernate, and during this time they must not be disturbed. Should they emerge at any time however, food must be provided. Some specimens have lived for five years or more in captivity.

Accommodation.—The most satisfactory way to maintain a pet hedgehog is to provide it with a large "run" in part of the garden. If wire-netting is employed it should be sunk under the ground to a depth of several inches, or the hedgehog will burrow underneath and escape. The

top of the run must be wired in, or alternatively there must be a "baffle board" or wire-frame (at least 9 in. wide) near the tope of the sides to prevent escape that way, for hedgehogs can scale wire-netting—and some other types of fence—with ease. There should be a warm, dry box for shelter, containing wood-wool or other bedding material. A simple but suitable shelter may be made out of a soap-box, preferably lined with asbestos sheeting or some other material impervious to water. A shallow sunken bath in the enclosure may be of interest, for hedgehogs take well to water, but the edges should be such that the hedgehog can get out easily.

If it is decided to keep a hedgehog indoors, then the best accommodation is probably similar to that described for ferrets.

Feeding.—The simplest diet consists of milk, some bread, and minced lean meat. Cooked meat is preferred to raw, but raw liver should be given occasionally. Another satisfactory diet comprises meat offals, "root" vegetables (*e.g.*, carrot, potato, and swede), and wheaten wholemeal biscuit, steamed together until cooked, and then mixed and minced with a small proportion of raw liver. A small quantity (say 1–2 per cent.) of mineral mixture is also desirable, and milk should be given freely. Although hedgehogs appear to drink but little water, a fresh supply should always be provided.

Breeding.—During the breeding season marked changes occur in both males and females, and the structures associated with reproduction increase enormously in size from about March onwards. The female is capable of having two litters a year, the first in May or June and the second in August or September. The period of gestation has not been determined exactly, but is believed to be thirty-five days, possibly with variations of up to well over forty days. During the breeding season the males are very pugnacious towards each other if females are with them, and may do each other considerable damage. (The mixing of strange hedgehogs is often a difficult procedure anyway, for they often fight and inflict nasty bites on one another's feet.)

The litter size is usually four to six, and the young, which have "soft" spines, are suckled by their mother for nearly six weeks. The young can partake of some solid food at about three weeks, and there is some evidence that if left with their mother for longer than six weeks she may compete unfairly with them for food!

Diseases.—Hedgehogs in captivity are susceptible to *respiratory infections*, and can sometimes contract certain strains of *human influenza*. They are susceptible also to *Salmonellosis* (see under mice and guinea-pigs). Fleas and other external parasites have been mentioned; these often disappear spontaneously as the hedgehog begins to thrive in captivity, but if not they should be dealt with by modern methods.

LAND TORTOISES.

Tortoises are popular pets, but although many are kept with great success in Great Britain, the majority of those that are imported each year are never looked after adequately, or fail to thrive for other reasons.

Most land tortoises that are imported into Great Britain for sale through dealers are: (1) the Spur-thighed Mediterranean Land Tortoise (*Testudo graeca*), commonly known as the "Moroccan tortoise" and sometimes as the "Iberian" or "Algerian"; or (2) Hermann's Tortoise (*Testudo hermanni*). The second is distributed in Southern France, Southern Italy, the larger islands of the Western Mediterranean, and parts of Yugoslavia, Albania, and Greece. There is a species found in Greece, the Margined Tortoise (*Testudo marginata*), but while adaptable to life in Great Britain, it is more difficult to acquire. The two common species differ in several ways, the "Moroccan tortoise" having a small bony spur on the back of the thigh. (The upper part of the shell is termed the carapace and the ventral portion the plastron.)

In selecting a tortoise one should ensure that the animal appears healthy. It should be active and withdraw quickly into its shell on being disturbed. Its legs should be firm and not limp, and there should be no abnormal discharge from the eyes or nostrils. The shell and limbs should be uninjured. Females are generally larger and have a shorter tail than the male. The shield above the tail is flat in the former and curved in the male. It is a good idea to obtain a pair or more of tortoises, but not more than can be looked after with care. On being purchased they should be washed in tepid water.

Many tortoises are given free range in gardens, but this is not advised with all, as they eat a wide variety of vegetables and young plants, and being wandering animals are liable to get lost if the garden is not completely fenced or walled. They should be provided with as large a "pen" or "run" as possible, the walls or wire netting of which should be high enough to prevent their climbing over. The practice of tethering tortoises by a hole in the shell should be discouraged. They should always be provided with a box or shelter, the cheapest form being a wooden soap box turned on one side and with a sufficiently wide entrance, the wood being creosoted and covered with roofing felt. It can be lined with asbestos sheeting if desired, and have its floor covered with dry leaves or other bedding material. Some other shelter should also be provided in the run. The tortoises should be bathed during the hot weather. The occasional application of olive oil will keep the shell polished.

Land tortoises must be fed daily, and it is important to allow them to build up good reserves to enable them to hibernate through the winter successfully. Suitable foods include lettuce, young cabbage, peas, clover, dandelions, and a wide variety of green plants and ripe, sweet fruits. Generally bread and milk should be avoided. For young tortoises especially, it is recommended that once weekly or so the food should be sprinkled with powdered cuttlefish bone, or better still a small quantity of powered calcium gluconate or cod-liver oil. Fresh water in a shallow tray, or even a saucer, should always be provided.

One of the most difficult problems in tortoise keeping is hibernation. Some persons avoid allowing their pets to hibernate by transferring them to a warm place, such as a heated greenhouse; if this is done they must be kept well fed and their place maintained at a summer temperature. It is imperative to do one thing or the other—the half-torpid tortoise that is neither hibernating nor kept at summer temperature will die. Moreover, a tortoise that is allowed to hibernate must not be disturbed.

Signs of pending hibernation, including sluggishness and lowered appetite, are usually evident late in September or early in October. Tortoises living in the garden may commence to bury themselves. If this is allowed they must be well covered, else they may be killed by the ensuing frost. It is, though, more convenient and perhaps provides a greater chance of survival, due to the changeable winter conditions in Britain, to place the animal in a large box, which should be packed with straw, leaves, or hay. The box should be stored in a cool but frostproof place, such as out-building, cellar, or attic. It is important not to create conditions that will awaken the tortoise or tempt it to emerge before the following spring. Rats have been known to attack hibernating tortoises, and so due precautions should be taken.

On emerging from hibernation the eyes and nostrils are somewhat sealed, and should be released by bathing with a 4 per cent. boric acid solution and warm water.

Recently imported female tortoises frequently lay eggs, but it is not a common occurrence for pairs to breed freely in Britain. During the early part of the summer the male is sometimes seen butting the shell of the female, this being a courtship action. If eggs are laid it is unlikely that they will be fertile, and less likely that they can be hatched. They have been hatched by placing them on damp sand and storing them in a warm place—a heated greenhouse or airing cupboard. The eggs should not be disturbed or "turned" once incubation has commenced.

Tortoise ticks are often present on freshly imported specimens, and may best be removed by damping the tick with paraffin or methylated spirits and then removing it gently with tweezers. Round worms are very numerous in tortoises, and should they be seen in the faecal matter the remainder may be eliminated by sprinkling up to one grain of powdered santonin on the food once a week for six weeks. Possibly, some of the newer, safe anthelmintic preparations containing piperazine derivatives may be equally effective. Eye infections are common, and are usually remedied by bathing the eye well with a 4 per cent. boric acid solution or warm cod-liver oil. Continuous discharge from the nose indicates lung infection, and as a primary measure the animal should be kept warm. Bleeding can be stopped by using Friar's Balsam, and care should be taken to prevent insects settling on open wounds.

WATER TORTOISES (TERRAPINS).

In Great Britain the tortoises that have become adapted to life in ponds and rivers are usually termed "terrapins," the name turtle being applied to marine forms. In the U.S.A. and Canada, however, not only the marine species but also terrapins and tortoises are all termed "turtles."

Several kinds of terrapin are available and capable of thriving in Great Britain. These include several American species, the European Pond Tortoise (*Emys orbicularis*), the Spanish Terrapin (*Clemmys leprosa*), the Caspian Terrapin (*Clemmys caspica*), and the Reeves' Terrapin (*Chinemys reevesii*), which hails from China and Japan.

The ideal place in which to keep terrapins is a garden pond within an enclosure. The pond should contain an "island" of dry ground on to which the animals can climb easily. The water should vary in depth, and at one point be at least 2 ft. deep. Provided that there is a suitable "island" the boundary walls of the pond can be upright to prevent escape. The final coat of cement should be smooth and mixed with a waterproofing agent. Shade should be available, not only on the island but also in some parts of the water. This may be provided by suitable plants.

Terrapins are almost entirely carnivorous, although the young of some species may take a little lettuce or other vegetable food. Suitable foods include *small* pieces of raw meat, raw liver (this should certainly be given from time to time), fish, and earthworms. Terrapins prefer to take their food in the water, and it is best to feed them individually if there are several, to ensure that each receives his proper share.

Water tortoises also hibernate. Some bury themselves in mud or sand at the bottom of their ponds, others will dig themselves into the earth in the island or banks of their pond, while others again may go to sleep in the box that, as in the case of land tortoises, should preferably be provided for them on part of ther "land." Should they sleep at the bottom of the pond, it is as well to prevent freezing of the water. One means of doing this is to leave a log or logs floating on the surface. Moving these logs on cold mornings will help to break any ice formed and to prevent total freezing.

AQUARIUM FISH.

There are two types of aquaria—the cold-water, for fish from this and other temperate countries, and the heated, for tropical varieties of fish. Apart from the fact that a suitable heating mechanism—usually electric, with thermostatic control—has to be maintained for tropical aquaria, the general principles governing the two types are much the same. There is a certain amount of additional initial expense in setting up a heated aquarium—the running costs are not high—but in some respects tropical fish are easier to maintain than many of the cold-water varieties.

It should be emphasised at the outset that those who want to keep fish should invest in a proper aquarium and not in a "goldfish bowl," unless the latter be very large in relation to the fish to be kept. Far too many fish suffer from overcrowding or from lack of sufficient water surface. In the case of cold-water fish, it has been calculated that every "1 in. of body" requires 1 sq. ft. of water surface in order to obtain sufficient oxygen for respiration. Thus a fish the body of which (*i.e.*, the length minus the tail fins) is 4 in. will require at least 4 sq. ft. of water surface, *i.e.*, an area of 2 ft. × 2 ft. Two such fish will require twice this area, and so on. In *The Right Way to Keep Pet Fish* by R. Dutta (6s.), it is pointed out that a goldfish should normally live for twenty-five years in a suitable pond, and grow to its full length of over 14 in. There are few indoor aquaria capable of supporting many full-grown goldfish in adequate conditions, and indeed it is recommended that fish such as shubunkins, fantails, veiltails, and orandas, which grow more slowly, are far better adapted to cold-water aquaria than goldfish. Tropical fish of the varieties kept in aquaria are usually much smaller. Many have an average body length of only about 1¼ in., and eighteen such fish may be maintained in a suitably heated tank with an area of water surface of 18 in. × 12 in.

A beginner should not only read good books on the subject (including *Water Life* publications) but also consult experts and his local aquarist or dealer. Whatever aquarium is chosen, the conditions should be correct *before* any fish are introduced. Should fish be suddenly acquired, before a proper aquarium has been fitted up for them they should be kept in some temporary (but sufficiently capacious) quarters until the aquarium is ready.

The instructions for installing and fitting up an aquarium are usually supplied, and should be followed carefully. The sand that is usually placed on the bottom should be thoroughly washed, and is best put in a little at a time. Make sure that the inside of the aquarium is thoroughly clean before anything at all is put into it. Ornamental rocks may next be introduced, and great care should be taken to ensure that these are of the correct type, unlikely to harm the fish physically or chemically. Water is then added very gently indeed, and suitable plants set. In the case of large tanks the planting is best done when the tank is only partly filled with water, but in any event the plants themselves should be kept wet all the time, or they may quickly shrivel up. In the case of cold-water aquaria everything may now be left for a few days—preferably a week or more—to ensure that all is well, and to allow certain micro-organisms that help form the food of the fish to develop. In the case of heated aquaria it is necessary also to ensure that the thermostat is working correctly and that the temperature is remaining constant or within very narrow limits. Here again it is advisable to wait at least a week before introducing any fish. Should conditions "go wrong" before or after the fish are introduced, it is best to start filling the tank all over again.

Fish should not be overfed, although regular feeding is essential. Attention must be paid to the feeding instructions issued with prepared fish foods, and to details given by the supplier of "live" foods. Provided fish are neither overcrowded not overfed, the amount of sediment that accumulates in the tank will not be excessive, but it should be siphoned away gently every month, or more often if necessary. Water lost by evaporation should be replaced, and in the case of heated tanks especially, it is most desirable that the added water be of the same temperature as that already in the tanks.

Certain species of water snail are often placed in aquaria to act as scavengers. It is necessary to ensure that, if snails are kept, they are of the right type, and it is important to consult experts on this matter.

Breeding is an interesting topic, there being both egg-laying and viviparous or "live-bearing" fish. The beginner is well advised to learn first how to keep fish in healthy condition in his aquarium before indulging in any planned breeding, and he should study the relevant information in books on the subject.

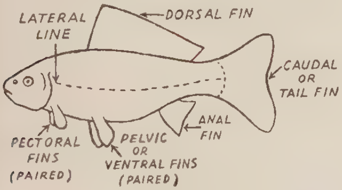
An aeration plant is often recommended on the grounds that it will increase the fish-carrying

capacity of the aquarium. This is true up to a point, but overcrowding may bring other troubles besides those connected with lack of sufficient oxygen, and the golden rule is never to keep too many fish for the size of aquarium in question. Another factor to be remembered is that should the aerator break down it may leave the fish with less oxygen than their proper requirement. It has been recommended that an aerator is best thought of as a stand-by, to be employed only in emergencies, *e.g.*, when for some reason extra fish have to be added to a tank already holding all or almost all its proper capacity.

There are unfortunately many diseases of fish, and as yet scientific knowledge concerning many of them is far less detailed than it should be. It is clear, however, that environmental factors are responsible for many deaths or cases of unthriftiness, and among the factors concerned may be listed: overcrowding, overfeeding, the provision of a diet that is qualitatively inadequate, lack of " balance " in the aquarium leading to unsuitable conditions, dirt, too strong light, lead paint and noxious substances, that may somehow have come into contact with the water (*e.g.*, from the hands of the person tending them) or been absorbed from the atmosphere. One must be careful of such things as disinfectants, soaps, petrol, etc. In the case of tropical fish the temperature of the water may be incorrect. Should fish troubles occur, therefore, it is as well to consider these various possibilities, although one should not hesitate to seek professional advice where there appears to be a case of infectious disease. An ailing fish should certainly be removed from the tank (assuming that there are other fish present) and given separate quarters of its own if such a course is feasible.

It is not intended to provide a description of the separate diseases, although it may be mentioned that such signs as the appearance of material resembling cotton-wool (actual fungal growths) and " rotting " of the tail or fins, are among those that should lead the owner to isolate affected fish and to seek help immediately.

No attempt is made here to describe any of the many different species and varieties of fish suitable for private aquaria. Some of the " points "



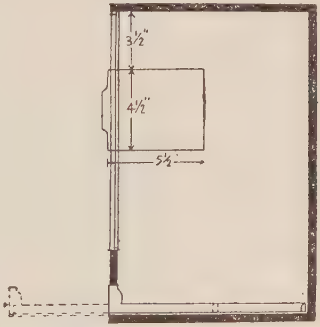
of a fish are shown in the accompanying illustration. Great care must be taken in mixing species, *e.g.*, " hard mouthed " and " soft mouthed " kinds should not be kept together. The temptation to put other species (*e.g.*, newts) with aquarium fish must likewise be avoided.

CAGE BIRDS.

Very many species and varieties of birds are now maintained successfully in captivity, and there exists in Great Britain a large and expanding " cage-bird fancy," that caters for a considerable proportion of the smaller birds adapted to cage or aviary life. The increase in the numbers of budgerigars since the end of the Second World War has been phenomenal, and it was estimated during 1957 that the numbers of the species alone in the United Kingdom exceeded 6 millions, the corresponding figure for the U.S.A.—where the popular name is " parakeets "—being over 18 millions.

The different types and sizes of birds have different requirements, and in the space available it is not possible to do more than cover the general principles and to deal briefly with the special characteristics of the management of the more easily maintained species. The beginner is advised to restrict his attention to one of the better-known species, *e.g.*, canaries or budgerigars, and not to attempt to maintain exotic varieties until he has acquired considerable experience.

Most species thrive best in aviaries, which may be indoor, outdoor, or of the combined " outdoor–indoor " type. An indoor aviary is usually all-wire and portable. The criticism of many such aviaries is that they tend to be high and narrow, whereas a fairly large floor-space is desirable. They should not be placed in cold or draughty places, nor too near a fire. If sited so as to receive much direct sunlight they must have adequate shelter. The wires must be close together, especially if smaller species are kept, a distance between them of about ⅜ in. being generally suitable. An outdoor aviary—suitable only for some species or at certain times in the case of others—should occupy a sunny position, although it too must include shade, and must be protected from winds. There ought in fact to be a sheltered portion, dry and well protected from the elements. The aviary must be strongly made and safe from all predators, including rats and mice. While it is often considered desirable to allow herbage to protrude through the wire-mesh floor, it is essential that the birds are never in close contact with wild rodents or their droppings. Most birds are highly susceptible to some forms of *salmonellosis* (see under mice and guinea-pigs), and can contract them in this way. It is advisable also that the roof of the aviary is solid: corrugated asbestos sheeting, projecting well clear of the edges of the uprights so as to prevent water and other matter from entering the interior, is excellent. The droppings of wild birds may be a potent source of bacterial infection or of internal parasites. To prevent close contact otherwise with wild birds, the wire or wire-netting " walls " of the aviary may be double. If an " outdoor–indoor " aviary is employed, there is usually an indoor flight cage, separated from the external portion either by a very light hanging door of suitable size, through which the birds can easily push their way, or by a sliding partition that the owner can operate as required.

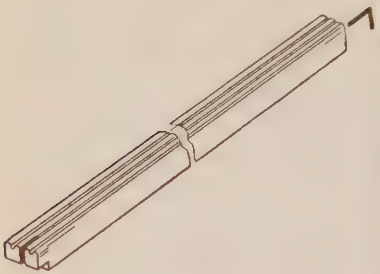


SECTION THROUGH CAGE.

If an aviary is out of the question, then a suitable cage should be purchased or constructed. The cage need not be ornate—indeed simplicity of design usually facilitates the highly important task of keeping everything clean—but it must be large enough. A cross-section through a breeding-cage suitable for canaries, and for many other species, is shown in the accompanying illustration. Such a cage should measure about 40 in. in length × 12 in. wide × 18 in. high. It is constructed of wood or some suitable sheeting except for the front, which consists of vertical wires with horizontal stays, and can be divided into two parts by means of a suitable partition containing a removable section made of wire. By this means the cock and hen canaries can be introduced into the separate sections and develop a courtship before being allowed to be together for actual mating. The cross-section indicates the site and size of the removable portion of the partition, and it shows also the removable tray that is such an

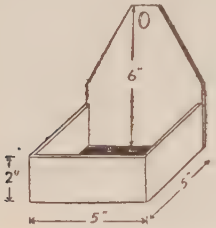
excellent fitting for almost any type of cage, and which greatly facilitates cleaning.

Whether an aviary or a cage is employed, it is essential to have proper fittings, including con-



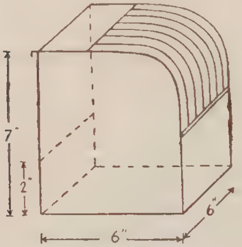
PERCH.

veniently placed drinking-troughs, feeding-trays and bird-baths, and good perches. Much unnecessary discomfort is brought about through the use of unsuitable perches, or ones that are incorrectly situated or not sufficiently "firm."



NESTING-BOX WITH PLAIN WOOD BOTTOM.

A suitable type of perch, of which there should be several in the cage or aviary, is shown in the accompanying illustration, and it should be of the appropriate dimensions for the size of bird. In the case of the larger canaries (Norwich and

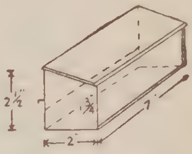


BIRD BATH.

Yorkshire), *e.g.*, the sectional measurements should be $\frac{5}{8}$ in. × $\frac{3}{4}$ in., whereas for a smaller canary (Border) they should be $\frac{1}{2}$ in. × $\frac{3}{4}$ in. The type of perch shown is easy to clean and does not possess awkward corners in which parasites may be harboured. The dimensions of a nesting box a bird-bath, and a feeding-tray suitable for canaries are also given in the accompanying illustrations.

While wood is a convenient material for aviary and cage construction, it has, of course, several disadvantages. Out of doors it is best creosoted (lead paint must never be used for places in which birds or other small animals are kept), and indoors it is better lined with hard asbestos sheeting. Metal is suitable—provided that it does not rust or corrode and that the environmental conditions are warm enough.

In all cases a supply of clean, fresh water should be available. Strict cleanliness should be observed, and professional advice taken immediately if a bird is not thriving.



SEED TROUGH.

CANARIES (*Serinus canarius*).—These are domesticated forms of the race of wild serin found in the Canary Islands, and may live up to twenty-five years. Many varieties are known, and although most individuals are "canary yellow," other colours have been developed by fanciers. Many books have been written about the canary, although there is still much to be learned concerning its feeding and diseases—as is indeed the case with almost all cage-birds. The system of feeding generally recommended is based upon a mixture of 2 or 3 parts of canary seed (which is rich in energy, and which is sometimes mixed with a little millet seed) to 1 part of summer rape seed, which is high in fat and protein. There seems to have been some difficulty in obtaining suitable rape seed in some areas since the war. The best is German summer rape or Rübsen rape. Other seeds are employed as substitutes, or for special purposes, *e.g.*, niger is usually added at breeding time, and linseed if there is any indication of premature or soft (out-of-season) moult. Good proprietary seed mixtures are available. A little greenfood should be provided twice weekly, and a piece of cuttlefish bone placed between the wires is a suitable source of calcium. Soft-bill food (containing boiled egg, dried egg yolk, dried flies, and ants' pupæ) is also recommended by many breeders, while others give chopped egg alone. Others again favour milk, especially for young birds.

Breeding is usually started late in March or early in April, but not unless the daily shade temperature is at least 50° F. The pairs should be selected earlier than this and transferred to breeding-cages, with the partition in position. By the middle of February the wire partition may be installed so that the two birds can see one another. A little niger seed is usually added to the diet, while finely ground oystershell or eggshell may be sprinkled on the floor. (Otherwise the floor may be covered with washed sand that is not too fine and is free from dust.) When the birds begin to feed one another through the wire they are ready for mating, and the partition may be removed. The nest-box can then be inserted and suitable nesting materials, *e.g.*, cow hair and moss, placed in the cage. The incubation period is thirteen to fourteen days. After the eggs are laid some owners prefer to separate the cock and the hen, but allow him to rejoin her after the young are all about eight to nine days old and have opened their eyes. If it is desired that all the chicks be hatched together, then one can remove the first three eggs that are laid—usually one egg is laid daily—and keep them in a box at room temperature, substituting dummy eggs for them in the nest-box. On the afternoon of the third day of laying they are returned to the nest-box in place of the dummies.

When the young chicks are able to feed for themselves they should be provided with special food, such as egg and bread crumbs and a little cracked canary seed. If the cock bird interferes with them, or causes the hen to neglect them, he must be returned to his own section. Usually, however, all goes well, and the hen will go to the nest again when the first chicks are almost sixteen days old. Some three or four broods may be raised in a season.

WAXBILLS, FINCHES, AND OTHER SEED-EATERS.—The canary is of course a finch, but most of the other "foreign finches" are considered by dealers and writers together with other types of seed-eating birds. Well over 30 species of *Avadavats*, *Buntings*, *Mannikins*, *Cardinals*, *Whydahs*, *Weavers*, and *Finches* of various descriptions have been maintained successfully in capitivity in Great Britain. One of the most popular is the *Zebra finch* (*Taeniopygia castanotis*), from Australia, which has bred so successfully in this country that supplies no longer depend upon fresh importations, and which is already appearing in several varieties. The native bird, and many of its descendants, are grey and white, with red beaks. The male bird has orange cheek-patches, and orange flanks with white markings. The throat has black barring on a white background, and indeed the characteristic markings of the male have been the subject of interesting behaviour studies. The female lacks these special markings. The species is hardy, and is capable of living in outdoor aviaries all the year round, so long as it has shelter from draughts or strong winds and adequate facilities for roosting. If provided with nest-boxes, the birds will attempt—often successfully—to breed all the year round, so to avoid overbreeding it is better to remove these boxes in winter. A mixture of millet and canary seed forms the basis of their diet, which should be supplemented with fresh greenfood, millet sprays, fine grit, and cuttlebone—and, of course, fresh water should be available. Another bird suitable for the relatively uninitiated bird-keeper is the *Bengalese* (a domestic variety of *Munia striata*). It seems that these birds are the result of careful breeding by the Japanese, and may be regarded as fertile hybrids. Three main forms, the Chocolate-and-White, the Fawn-and-White, and the White, have been developed. These birds will thrive in cages or in aviaries. As in the case of Zebra Finches, they will attempt to breed all the year round if provided with nest-boxes. Bengalese are sociable birds, sometimes known in the U.S.A. as Society Finches. They appear to require less additional food than most species, thriving on a mixture of canary and millet seed, together with grit, cuttlebone, and an occasional millet spray or item of greenstuff.

For details of these birds, and of the many others from which a selection may be made, works of reference should be consulted. Three very useful books, all published by Cage Birds, London, are *Foreign Bird Keeping*, by Edward J. Boosey (63*s*.), *Foreign Birds for Beginners*, by D. H. S. Risdon (10*s*. 6*d*.), and *Foreign Birds for Garden Aviaries*, by Alec Brooksbank (10*s*. 6*d*.).

BUDGERIGARS.—The increase in the popularity of this bird has been phenomenal, although to those who have experience of other birds as pets the reasons are soon fairly obvious. Apart from the capacity to talk, shown by many birds—especially males—kept alone and trained, there is a liveliness, almost a "cheekiness," and an apparent like of human companionship. The wild green budgerigar (*Melopsittacus undulatus*) exists in large numbers in the grassland and desert shrub regions of Australia. The usual colour is grass green—it is frequently known as the Grass Parakeet—with a yellow mask, with three black spots on either side. As a result of intensive breeding, a considerable number of colour varieties has been produced, and the genetics of colour are a constant source of interest to budgerigar breeders. A vast budgerigar "fancy" has been built up in the United Kingdom, the U.S.A., and other countries, and World Budgerigar Congresses are held every few years. Budgerigars will thrive in outdoor aviaries all the year round, but the vast majority are kept as indoor pets in cages or small aviaries. The cages can be similar to those used for canaries, and care should be taken that the perches are of the correct diameter. If nest-boxes are put up, and the environmental conditions are suitable, budgerigars suitably paired will breed at almost any time of the year. It is customary, however, to restrict breeding to the spring, summer, and early autumn. Overbreeding may lead to difficulties, including the production of "runners" or "French moult." The sexes may normally be distinguished, at any rate in mature individuals, by the colour of the cere at the base of the beak, which is blue in males and brown in females. Males may lose their colour if not in good condition and for other reasons.

There are now many proprietary seeds mixtures, but some owners prefer to make up their own mixtures of millet (usually mixing small yellow and large white varieties) and canary seed. Millet sprays, fresh greenfood, good grit, and cuttlebone are all desirable, and it is important that the correct size and consistency of grit be chosen. Variety in "extras" to the basal seeds diet is probably important, for the captive bird has not the same opportunities as its wild ancestors for ranging widely for, possibly, important trace items of food. Breeding birds secrete a "milk," comparable with the crop milk of pigeons and some other birds, and this is of importance in the early feeding of the young.

Most healthy budgerigars seem to live to the age of 5–7 years or more, and considerably greater ages have been attained in captivity.

Such is the development of the budgerigar fancy that most equipment as well as food can be obtained ready for use. The playful habits of budgerigars have led to their being given table-tennis balls or a variety of small toys to play with, while some forms of food are supplied as budgerigar bells or otherwise in special shapes that seem to amuse the birds as they take the constituent seed from them.

The study of budgerigar diseases is in its infancy, but already some important facts have become realised. *French moult* is certainly reproducible by overbreeding, and may be linked with deficiencies in the ability of the parent birds to feed their young—or to hand over to them at the time of laying sufficient nutritional reserves to carry them through hatching and parental feeding until the time that they can fend for themselves. A deficiency in the "milk" has been shown in some cases, and may be generally true. Large chicks can be produced by killing off or removing all but a single member of the clutch, and allowing the parents to deal with it alone.

A mite infestation, due to *Cnemidocoptes pilae*, may give rise to *Scaly face*, *Scaly beak*, or *Scaly leg*, for which veterinary treatment is now available. Another condition, known as *Brown hypertrophy of the cere*, is characterised by thickening and darkening of the surface of the cere. In the early stages it is sometimes thought that the bird is changing its sex. There is no known successful treatment at the time of writing, and if the overgrowth is cut away it will only reform. There are various disturbances of the *digestive tract*, and some of these may be associated with inability to stand properly.

There are many treatises on the budgerigar. A useful little work is *Budgerigar Guide*, by Cessa Feyerbrand (Fond du Lac, Wisconsin: All-Pets Magazine).

LOVEBIRDS AND PARROTLETS are also members of the parrot family, and while they are unlikely to equal the budgerigar in popularity, they are nevertheless interesting birds that are being kept in increasing numbers as pets. Lovebirds, of the genus *Agapornis*, are African in origin, and some six species are commonly kept in captivity. Parrotlets derive from South America, the commonest species being the Guiana Parrotlet, *Forpus passerinus*. Both types of bird are relatively simple to maintain in aviaries or large cages, and their basal diet (which should be supplemented widely) is a mixture of millet and canary seed. They are hardy and vigorous creatures, many details of which are to be found in condensed form in *Lovebirds and Parrotlets*, by C. P. Luke (London: Cage Birds, 8*s*. 6*d*.).
